The provocative and counterintuitive force of Rorty's treatment of rationality and science in terms of conversational ethics is undeniable. It is important to realize, though, that Rorty is not denying that there is any bona fide use of notions like truth, knowledge, or objectivity. Rather his point is that our ordinary uses of these notions always trade for their content and point on particular features of their varying contexts of application. His further point is that when we abstract away from these different contexts and practices, in search of general notions, we are left with pure abstract hypostatizations incapable of providing us with any guide to action at all. The upshot, Rorty holds, is that we simply do not have a concept of objective reality which can be invoked either to explain the success of some set of norms of warrant, or to justify some set of standards over against others. This is perhaps clearest in Rorty's treatment of the concept of truth. With regard to truth, Rorty's rhetoric and philosophical strategy has indeed shifted over the last three decades. As late as in 1982 (in CP) he still attempts to articulate his view of truth by drawing on William James's famous definition in terms of what is good in the way of belief. Soon after this, however, Rorty comes to doubt the point of any theory of truth, and, following Davidson's lead explicitly rejects all attempts to explicate the notion of truth in terms of other concepts. Rorty's mature view of of the point and significance of the concept of truth is first elaborated in "Davidson, Pragmatism and Truth," in ORT. Recent expressions are found in the first of the two Spinoza Lectures given at the University of Amsterdam in 1997, "Is it Desirable to Love truth?", in the paper, "Is Truth a Goal of Inquiry? Donald Davidson versus Crispin Wright" (TP), as well as in the introductions to, respectively, TP and PSH. In these writings Rorty argues that while "truth" has various important uses, it does not itself name a goal towards which we can strive, over and above warrant or justification. His argument is not that truth is reducible to warrant, but that the concept has no deep or substantive criterial content at all. That is, there are only semantic explanations to be offered for why it is the case that a given sentence is true just when its truth conditions are satisfied. So aiming for truth, as opposed to warrant, does not point to a possible line of action, just as we have no measure of our approximation to truth other than increasing warrant. Indeed, for Rorty, this is part of what makes the concept so useful, in a manner

not coincidentally analogous with goodness; it ensures that no sentence can ever be analytically certified as true by virtue of its possession of some other property. Rorty's attitude to the concept of truth has been much criticized, often on the ground that the very notion of warrant, indeed the concept of belief in general, presupposes the notion of truth. However, it may be that we can do justice to these connections without supposing that the notion of truth thus involved backs up the notions of belief and warrant with any substantive normative content of its own. Indeed, that neither the concept of truth, nor those of objectivity and of reality, can be invoked to explain or legitimate our inferential practices and our standards of warrant, is the essence of Rorty's conversationalism, or epistemological behaviorism.

3. Pragmatized Culture

Taking epistemological behaviorism to heart, Rorty urges, means that we can no longer construe the authority of science in terms of ontological claims. Though many disagree, this is not, for Rorty, to denigrate or weaken the authority of science. Indeed, a prominent feature of Rorty's post-metaphysical, post-epistemological culture, is a thoroughgoing Darwinian naturalism.

3.1 Naturalism

To be a naturalist in Rorty's sense,

> is to be the kind of antiessentialist who, like Dewey, sees no breaks in the hierarchy of increasingly complex adjustments to novel stimulation--the hierarchy which has amoeba adjusting themselves to changed water temperature at the bottom, bees dancing and chess players check-mating in the middle, and people fomenting scientific, artistic, and political revolutions at the top. (ORT 109)

In Rorty's view, both Dewey's pragmatism and Darwinism encourage us to see vocabularies as tools, to be assessed in terms of the particular purposes they may serve. Our vocabularies, Rorty suggests, "have no more of a *representational* relation to an intrinsic nature of things than does the anteater's snout or the bowerbird's skill at weaving." (TP 48)

Pragmatic evaluation of various linguistically infused practices requires a degree of specificity. From Rorty's perspective, to suggest that we might evaluate vocabularies with respect to their ability to uncover the truth, would be like claiming to evaluate tools for their ability to help us get what we want--full stop. Is the hammer or the saw or the scissors better--in general? Questions about usefulness can only be answered, Rorty points out, once we give substance to our purposes.

Rorty's pragmatist appropriation of Darwin also defuses the significance of reduction. He rejects as representationalist the sort of naturalism that implies a program of nomological or conceptual reduction to terms at home in a basic science. Rorty's naturalism echoes Nietzsche's perspectivism; a descriptive vocabulary is useful insofar as the patterns it highlights are usefully attended to by creatures with needs and interests like ours. Darwinian naturalism, for Rorty, implies that there is no one privileged vocabulary whose purpose is to serve as a critical touchstone for our various descriptive practices.

For Rorty, then, any vocabulary, even that of evolutionary explanation, is a tool for a purpose, and therefore subject to teleological assessment. Typically, Rorty justifies his own commitment to Darwinian naturalism by suggesting that this vocabulary is suited to further the secularization and democratization of society that Rorty thinks we should aim for. Accordingly, there is a close tie between Rorty's construal of the naturalism he endorses and his most basic political convictions.

3.2 Liberalism

Rorty is a self-proclaimed romantic bourgeois liberal, a believer in piecemeal reforms advancing economic justice and increasing the freedoms citizens are able to enjoy. The key imperative in Rorty's political agenda is the deepening and widening of solidarity. Rorty is sceptical toward radicalism; political thought purporting to uncover hidden, systematic causes for injustice and exploitation, and on that basis proposing sweeping changes to set things right. (ORT Part III; EHO; CIS Part II; AC) The task of the intellectual, with respect to social justice, is not to provide refinements of social theory, but to sensitize us to the suffering of others, and refine, deepen and expand our ability to identify with others, to think of others as like ourselves in morally relevant ways. (EHO Part III; CIS Part III) Reformist liberalism with its commitment to the expansion of democratic freedoms in ever wider political solidarities is, on Rorty's view, an historical contingency which has no philosophical foundation, and needs none. Recognizing the contingency of these values and the vocabulary in which they are expressed, while retaining the commitments, is the attitude of the liberal ironist. (CIS essays 3,4) Liberal ironists have the ability to combine the consciousness of the contingency of their own evaluative vocabulary with a commitment to reducing suffering--in particular, with a commitment to combatting cruelty. (CIS essay 4, ORT Part III) They promote their cause through redescriptions, rather than arguments. The distinction between argumentative discourse and redescription corresponds to that between propositions and vocabularies. Change in belief may result from convincing argument. A change in what we perceive as interesting truth value candidates results from acquiring new vocabularies. Rorty identifies romanticism as the view that the latter sort of change is the more significant. (CIS "Introduction", essay 1).

Rorty's romantic version of liberalism is expressed also in the distinction he draws between the private and the public. (CIS) This distinction is often misinterpreted to imply that certain domains of interaction or behaviour should be exempted from evaluation in moral or political or social terms. The distinction Rorty draws, however, has little to do with traditional attempts to draw lines of demarcation of this sort between a private and a public domain--to determine which aspects of our lives we do and which we don't have to answer for publically. Rorty's distinction, rather, goes to the purposes of theoretical vocabularies. We should, Rorty urges, be "content to treat the demands of self-creation and of human solidarity as equally valid, yet forever incommensurable." (CIS xv) Rorty's view is that we should treat vocabularies

for deliberation about public goods and social and political arrangements, on the one hand, and vocabularies developed or created in pursuit of personal fulfilment, self-creation, and self-realization, on the other, as distinct tools.

3.3 Ethnocentrism

Rorty's liberal ironist, recognizing--indeed, affirming--the contingency of her own commitments, is explicitly ethnocentric. (ORT "Solidarity or Objectivity") For the liberal ironist,

> ...one consequence of antirepresentationalism is the recognition that no description of how things are from a God's-eye point of view, no skyhook provided by some contemporary or yet-to-be-developed science, is going to free us from the contingency of having been acculturated as we were. Our acculturation is what makes certain options live, or momentous, or forced, while leaving others dead, or trivial, or optional. (ORT 13)

So the liberal ironist accepts that bourgeois liberalism has no universality other than the transient and unstable one which time, luck, and discursive effort might win for it. This view looks to many readers like a version of cultural relativism. True, Rorty does not say that what is true, what is good, and what is right is relative to some particular ethnos, and so in that sense he is no relativist. But the worry about relativism, that it leaves us with no rational way to adjudicate conflict, seems to apply equally to Rorty's ethnocentric view. Rorty's answer is to say that in one sense of "rational" that is true, but that in another sense it is not, and to recommend that we drop the former. Rorty's position is that we have no notion of rational warrant that exceeds, or transcends, or grounds, the norms that liberal intellectuals take to define thorough, open-minded, reflective discussion. It is chimerical, Rorty holds, to think that the force or attractiveness of these norms can be enhanced by argument that does not presuppose them. It is pointless, equally, to look for ways of convicting those who pay them no heed of irrationality. Persuasion across such fundamental differences is achieved, if at all, by concrete comparisons of particular alternatives, by elaborate description and redescription of the kinds of life to which different practices conduce.

4. Rorty and Philosophy

The broad scope of Rorty's metaphilosophical deconstruction, together with a penchant for uncashed metaphor and swift, broad-stroke historical narrative, has gained Rorty a sturdy reputation as an anti-philosopher's philosopher. While his writing enjoys an unusual degree of popularity beyond the confines of the profession, Rorty's work is often regarded with suspicion and scepticism within academic philosophy.

4.1 Critical Responses

As we have seen in connection with Rorty's attitude to science, it is particularly Rorty's treatment of truth and knowledge that has drawn fire from philosophers. While a great variety of philosophers have criticized Rorty on this general score in a great variety of ways, it is not very difficult to discern a common concern; Rorty's conversationalist view of truth and knowledge leaves us entirely unable to account for the notion that a reasonable view of how things are is a view suitably constrained by how the world actually is. This criticism is levelled against Rorty not only from the standpoint of metaphysical and scientific realist views of the sort that Rorty hopes will soon be extinct. It is expressed also by thinkers who have some sympathy with Rorty's historicist view of intellectual progress, and his critique of Kantian and Platonist features of modern philosophy. Frank B. Farrell, for instance, argues that Rorty fails to appreciate Davidson's view on just this point, and claims that Rorty's conversationalist view of belief-constraint is a distorted, worldless, version of Davidson's picture of how communication between agents occurs. Similarly, John McDowell, while also critical of Davidson's epistmeological views, claims that Rorty's view of the relation between agent and world as merely causal runs foul of the notion that our very concept of a creature with beliefs involves the idea of a rational constraint of the world on our epistemic states.

However, critics are concerned not only with what they see as a misguided view of belief, truth, and knowledge, whether relativist, subjectivist, or idealist in nature. An important reason for the high temperature of much of the debate that Rorty has inspired is that he appears to some to rejects the very values that are the basis for any articulation of a philosophical view of truth and knowledge at all. Rorty is critical of the role of argument in intellectual progress, and dismissive of the very idea of theories of truth, knowledge, rationality, and the like. Philosophers such as Hilary Putnam and Susan Haack have increasingly focussed on this aspect of Rorty's views. Haack, in particular, frames criticism of Rorty along these lines in moral terms; to her mind, Rorty's efforts to abandon the basic concepts of traditional epistemology are symptoms of a vulgar cynicism, which contributes to the decline of reason and intellectual integrity that Haack and others find to be characteristic of much contemporary thought. The charge of intellectual irresponsibility is sometimes raised, or at last implied, in connection with Rorty's use of historical figures. Rorty's reading of Descartes and of Kant i PMN have often been challenged, as has his more constructive uses of Hegel, Nietzsche, Heidegger, and Wittgenstein. The kind of appropriation of other writers and thinkers that Rorty performs will at times seem to do violence to the views and intentions of the protagonists. Rorty, however, is quite clear about the rhetorical point and scholarly limits of these kinds of redescriptions, as he explains in "The Historiography of Philosophy: Four Genres."

4.2 Claim to Pragmatism

One particularly contentious issue has arisen in connection with Rorty's appropriation of earlier philosophers; prominent readers of the classical American pragmatists have expressed deep reservations about Rorty's interpretation of Dewey and Peirce, in particular, and the pragmatist movement in general. Consequently, Rorty's entitlement to the label "pragmatist" has been challenged. Recently, Susan Haack's

strong claims on this score have received much attention, but there are many others. (See, for example, the discussions of Rorty in Thomas M. Alexander, 1987; Gary Brodsky, 1982; James Campbell, 1984; Abraham Edel, 1985; James Gouinlock, 1995; Lavine 1995; R.W: Sleeper, 1986; as well as the essays in Lenore Langdorf and Andrew R. Smith, 1995.) For Rorty, the key figure in the American pragmatist movement is John Dewey, to whom he attributes many of his own central doctrines. In particular, Rorty finds in Dewey an anticipation of his own view of philosophy as the hand-maiden of a humanist politics, of a non-ontological view of the virtues of enquiry, of a holistic conception of human intellectual life, and of an anti-essentialist, historicist conception of philosophical thought. To read Dewey his way, however, Rorty explicitly sets about separating the "good" from the "bad" Dewey. (See "Dewey's Metaphysics," CP, 72-89, and "Dewey between Hegel and Darwin, in Saatkamp, 1-15.) He is critical of what he takes to be Dewey's backsliding into metaphysics in *Experience and Nature*, and has no patience for the constructive attempt of *Logic: The Theory of Inquiry*. Rorty thus scheme of evaluation on Dewey's works which many scholars object to. Lavine, for instance, claims that "scientific method" is Dewey's central concept (Lavine 1995, 44). R.W. Sleeper holds that reform rather than elimination of metaphysics and epistemology is Dewey's aim (Sleeper 1986, 2, chapter 6).

Rorty's least favourite pragmatist is Peirce, whom he regards as subject to both scheme-content dualism and to a degree of scientism. So it is not surprising that Haack, whose own pragmatism draws inspiration from Peirce, finds Rorty's recasting of pragmatism literally unworthy of the name. Rorty's key break with the pragmatists is a fundamental one; to Haack's mind, by situating himself in opposition to the epistemological orientation of modern philosophy, Rorty ends up dismissing the very project that gave direction to the works of the American pragmatists. While classical pragmatism is an attempt to understand and work out a novel legitimating framework for scientific enquiry, Haack maintains, Rorty's "pragmatism" (Haack consistently uses quotes) is simply an abandonment of the very attempt to learn more about the nature and adequacy conditions of enquiry. Instead of aiding us in our aspiration to be govern ourselves through rational thought, Rorty weakens our intellectual resilience and leaves us even more vulnerable to rhetorical seduction. To Haack and her sympathisers, Rorty's pragmatism is dangerous, performing an end-run on reason, and therefore on philosophy.

4.3 Analytic Philosophy

Nevertheless, the founding impulses of Western philosophy clearly express themselves in Rorty's fundamental concern with the connection between philosophical thinking and the pursuit of human happiness. Rorty's relationship to the traditions of Western philosophy is more nuanced than his reputation might suggest. So, too, is Rorty's relation to analytical philosophy in particular. Rorty is sometimes portrayed as a renegade, as someone who went through a transformation from bona fide analytical philosopher to something else, and then lived to tell a tale of liberation from youthful enchantment. This portrayal, however, distorts both Rorty's view of analytical philosophy and the trajectory of his thinking.

In the mid nineteen sixties, Rorty gained attention for his articulation of eliminative materialism (cf., "Mind-Body Identity, Privacy and Categories," 1965). Around that time, he also edited, and wrote a lengthy introduction to, a volume entitled *The Linguistic Turn* (1967, reissued with a new introduction in

1992). Though the introduction to the 1967 volume and the early papers in philosophy of mind show Rorty adopting frameworks for philosophical problems he has since dispensed with, these writings at the same time clearly bear the mark of the fundamental metaphilosophical attitude which becomes explicit in the next decade. In the "Preface" to PMN, referring to Hartshorne, McKeon, Carnap, Robert Brumbaugh, Carl Hempel, and Paul Weiss, Rorty says,

> I was very fortunate in having these men as my teachers, but, for better or worse, I treated them all as saying the same thing: that a "philosophical problem" was a product of the unconscious adoption of a set of assumptions built into the vocabulary in which the problem was stated--assumptions which were to be questioned before the problem itself was taken seriously. (PMN xiii)

This way of stating the lesson, however, appears to leave open the possibility that certain philosophical problems eventually may legitimately be taken seriously--that is, at face value in the sense that they require constructive solutions--provided the assumptions which sustain their formulation stand up to proper critical scrutiny. Taken this way, the attitude Rorty here expresses would be more or less the same as that of all those philosophers who have diagnosed their predecessors' work as mixtures of pseudo-questions and genuine problems dimly glimpsed, problems which now, with the proper frame of questioning fully clarified, may be productively addressed. But the full force of the lesson Rorty learned emerges only with the view that this notion of proper critical scrutiny is illusory. For Rorty, to legitimate the assumptions on which a philosophical problem is based, would be to establish that the terms we require to pose it are mandatory, that the vocabulary in which we encounter it is in principle inescapable. But Rorty's construal of the linguistic turn, as well as his proposals for eliminating the vocabulary of the mental, are really at odds with the idea that we might hope to construct a definitive vocabulary for philosophy. Even in his early days, Rorty's approach to philosophy is shaped by the historicist conviction that no vocabularies are inescapable in principle. This means that progress in philosophy is gained less from constructive solutions to problems than through therapeutic dissolution of their causes, that is, through the invention of new vocabularies by the launch of new and fruitful metaphors. (PMN "Introduction"; ORT "Unfamiliar Noises: Hesse and Davidson on Metaphor")

To hold that no vocabulary is final is also to hold that no vocabulary can be free of unthematized yet optional assumptions. Hence any effort to circumvent a philosophical problem by making such assumptions visible is subject to its own circumvention. Accordingly, the fact that Rorty often distances himself from the terms in which he earlier framed arguments and made diagnoses is in itself no reason to impose on him, as some have done, a temporal dichotomy. It may be that Rorty's early work, inspired by a less critical, less dialectical reading of Quine and Sellars than that offered in PMN, is more constructive than therapeutic in tone and jargon, and therefore from Rorty's later perspective in an important sense misguided. However, what ties together all Rorty's work, over time and across themes, is his complete lack of faith in the idea that there is an ideal vocabulary, one which contains all genuine discursive options. Rorty designates this faith Platonism (an important theme in CIS). That there are no inescapable forms of description is a thought which permeates Rorty's work from the 1960s right through his later therapeutic articulations of pragmatism. These characterizations of pragmatism in terms of anti-foundationalism (PMN), of anti-representationalism (ORT), of anti-essentialism (TP) are explicitly

parasitic on constructive efforts in epistemology and metaphysics, and are intended to high-light the various ways that these efforts remain under the spell of a Platonic faith in ideal concepts and mandatory forms of descriptions.

Rorty's use of Quine and Sellars to make his fundamental points against the idea of philosophy as a knowledge legitimation project, as well as his articulation of his critique in terms of typically "analytical" philosophical problems, has contributed to an impression of PMN as an internal indictment of analytic philosophy as such. Many--some gleeful, some chagrined--have read PMN as a purported demonstration of the bankruptcy of one of the two contemporary main streams of Western philosophy. Such readers draw support for this view also from the fact that much of Rorty's writings since PMN has been concerned to show the virtues in thinkers like Heidegger and Derrida. (EHO) Twenty years later, however, it seems better not to superimpose the analytic-continental divide onto the message of PMN, or on Rorty. In PMN, his central point is that philosophy needs to break free from the metaphor of mind as a medium of appearances, appearances that philosophy must help us sort into the mere and the reality-corresponding ones. Rorty made this point in a vocabulary that was developed by Anglo-American (whether by birth, naturalization, or late adoption) philosophers in the course of the preceding half-century. It is not necessary, and probably misleading, to see Rorty's criticism of epistemology and the assumptions that make it appear worthwhile as a criticism of a particular philosophical style of philosophy or set of methodological habits. Reading PMN in conjunction with the essays in CP (see particularly essay 4, "Professionalized Philosophy and Transcendentalist Culture", essay 12, "Philosophy in America Today", and also "Introduction"), one quickly sees that the target of PMN cannot be a putative school or branch of the subject called "Analytic Philosophy". Because Rorty thinks philosophy has no essence, has no defining historical task, fails to mark out a special domain of knowledge, and is not, in short, a natural kind (CP 226), he leaves no ground from which to level that sort of critique. Nor is it his intention to do so. Around the time of the publication of PMN, Rorty's view of the matter was ‘that "analytic philosophy" now has only a stylistic and sociological unity’ (CP 217). He then qualifies this point as follows: "In saying....[this], I am not suggesting that analytic philosophy is a bad thing, or is in bad shape. The analytic style is, I think, a *good* style. The *esprit de corps* among analytic philosophers is healthy and useful." (CP 217) However, while Rorty apparently bears no prejudice against analytic philosophy in particular, the very reason for his tolerance--his antiessentialist, historicist view of philosophy and its problems--has for many critics been a point of objection. After his faint praise, Rorty goes on:

> All I am saying is that analytic philosophy has become, whether it likes it or not, the same sort of discipline as we find in the other "humanities" departments--departments where pretensions to "rigor" and to "scientific" status are less evident. The normal form of life in the humanities is the same as that in the arts and in belles-lettres; a genius does something new and interesting and persuasive, and his or her admirers begin to form a school or movement. (CP 217-218)

This is perfectly consonant with the attitude to the notion of philosophical method Rorty expresses 20 years later: "So-called methods are simply descriptions of the activities engaged in by the enthusiastic imitators of one or another original mind--what Kuhn would call the "research programs" to which their

works gave rise." (TP 10) Rorty's metaphilosophical critique, then, is directed not at particular techniques or styles or vocabularies, but toward the idea that philosophical problems are anything other than transient tensions in the dynamics of evolving, contingent vocabularies. If his critique has bite specifically against analytic philosophy, this may be because of a lingering faith in philosophical problems as lasting intellectual challenges that any honest thinker has to acknowledge, and which may be met by making progress in methodology. Rorty himself, however, nowhere says that this faith is part of the essence of analytical philosophy. On the contrary, it would seem that analytical philosophers, people like Sellars, Quine, and Davidson, have provided Rorty with indispensable critical tools in his attack on the epistemological legitimation-project which has been a central concern in philosophy since Descartes.

(ca. 1895, in *The Letters of William James*, ed. by Henry James, Boston, 1920)

William James

William James was an original thinker in and between the disciplines of physiology, psychology and philosophy. His twelve-hundred page masterwork, *The Principles of Psychology* (1890), is a rich blend of physiology, psychology, philosophy, and personal reflection that has given us such ideas as "the stream of thought" and the baby's impression of the world "as one great blooming, buzzing confusion" (PP 462). It contains seeds of pragmatism and phenomenology, and influenced generations of thinkers in Europe and America, including Edmund Husserl, Bertrand Russell, John Dewey, and Ludwig Wittgenstein. James studied at Harvard's Lawrence Scientific School and the School of Medicine, but his writings were from the first as much philosophical as scientific. "Some Remarks on Spencer's Notion of Mind as Correspondence" (1878) and "The Sentiment of Rationality" (1879, 1882) presage his future pragmatism and pluralism, and contain the first statements of his view that philosophical theories are reflections of a philosopher's temperament or vision.

James hints at his religious concerns in his earliest essays and in *The Principles*, but they become more explicit in *The Will to Believe and Other Essays in Popular Philosophy* (1897), *Human Immortality: Two Supposed Objections to the Doctrine* (1898), *The Varieties of Religious Experience* (1902) and *A Pluralistic Universe* (1909). James oscillated between thinking that a "study in human nature" such as *Varieties* could contribute to a "Science of Religion" and the belief that religious experience involves an altogether supernatural domain, somehow inaccessible to science but accessible to the individual human subject. James made some of his most important philosophical contributions in the last decade of his life.

In a burst of writing in 1904-5 (collected in *Essays in Radical Empiricism* (1912)) he set out the metaphysical view most commonly known as "neutral monism," according to which there is one fundamental "stuff" which is neither material nor mental. He also published *Pragmatism* (1907), the culminating expression of a set of views permeating his writings.

Chronology of James's Life

- 1842. Born in New York City, first child of Henry James and Mary Walsh. James. Educated by tutors and at private schools in New York.
- 1843. Brother Henry born.
- 1848. Sister Alice born.
- 1855-8. Family moves to Europe. William attends school in Geneva, Paris, and Boulogne-sur-Mer; develops interests in painting and science.
- 1858. Family settles in Newport, Rhode Island, where James studies painting with William Hunt.
- 1859-60. Family settles in Geneva, where William studies science at Geneva Academy; then returns to Newport when William decides he wishes to resume his study of painting.
- 1861. William abandons painting and enters Lawrence Scientific School at Harvard.
- 1864. Enters Harvard School of Medicine.
- 1865. Joins Amazon expedition of his teacher Louis Agassiz, contracts a mild form of smallpox, recovers and travels up the Amazon, collecting specimens for Agassiz's zoological museum at Harvard.
- 1866. Returns to medical school. Suffers eye strain, back problems, and suicidal depression in the fall.
- 1867-8. Travels to Europe for health and education: Dresden, Bad Teplitz, Berlin, Geneva, Paris. Studies physiology at Berlin University, reads philosophy, psychology and physiology (Wundt, Kant, Lessing, Goethe, Schiller, Renan, Renouvier).
- 1869. Receives M. D. degree, but never practices. Severe depression in the fall.
- 1870-1. Depression and poor health continue.
- 1872. Accepts offer from President Eliot of Harvard to teach undergraduate course in comparative

physiology.

- 1873. Accepts an appointment to teach full year of anatomy and physiology, but postpones teaching for a year to travel in Europe.
- 1874-5. Begins teaching psychology; establishes first American psychology laboratory.
- 1878. Marries Alice Howe Gibbens. Publishes "Remarks on Spencer's Definition of Mind as Correspondence" in *Journal of Speculative Philosophy*.
- 1879. Publishes "The Sentiment of Rationality" in *Mind*.
- 1880. Appointed Assistant Professor of Philosophy at Harvard. Continues to teach psychology.
- 1882. Travels to Europe. Meets with Ewald Hering, Carl Stumpf, Ernst Mach, Wilhelm Wundt, Joseph Delboeuf, Jean Charcot, George Croom Robertson, Shadworth Hodgson, Leslie Stephen.
- 1884. Lectures on "The Dilemma of Determinism" and publishes "On Some Omissions of Introspective Psychology" in *Mind*.
- 1885-92. Teaches psychology and philosophy at Harvard: logic, ethics, English empirical philosophy, psychological research.
- 1890. Publishes *The Principles of Psychology* with Henry Holt of Boston, twelve years after agreeing to write it.
- 1897. Publishes *The Will to Believe and Other Essays in Popular Philosophy*. Lectures on "Human Immortality" (published in 1898).
- 1898. Identifies himself as a pragmatist in "Philosophical Conceptions and Practical Results," given at the University of California, Berkeley. Develops heart problems.
- 1899. Publishes *Talks to Teachers on Psychology: and to Students on Some of Life's Ideals* (including "On a Certain Blindness in Human Beings" and "What Makes Life Worth Living?"). Becomes active member of the Anti-Imperialist League, opposing U. S. policy in Philippines.
- 1901-2. Delivers Gifford lectures on "The Varieties of Religious Experience" in Edinburgh (published in 1902).
- 1904-5 Publishes "Does 'Consciousness' Exist?," "A World of Pure Experience," "How Two Minds Can Know the Same Thing," "Is Radical Empiricism Solipsistic?" and "The Place of Affectional Facts in a World of Pure Experience" in *Journal of Philosophy, Psychology and Scientific Methods*. All were reprinted in *Essays in Radical Empiricism* (1912).
- 1907. Resigns Harvard professorship. Publishes *Pragmatism: A New Name for Some Old Ways of Thinking*, based on lectures given in Boston and at Columbia.
- 1909. Publishes *A Pluralistic Universe*, based on Hibbert Lectures delivered in England and at Harvard the previous year.
- 1910. Publishes "A Pluralistic Mystic" in *Hibbert Journal*. Abandons attempt to complete a "system" of philosophy. (His partially completed manuscript published posthumously as *Some Problems of Philosophy*). Dies of heart failure at summer home in Chocorua, New Hampshire.

Early Writings

"Remarks on Spencer's Definition of Mind as Correspondence" (1878)

James's discussion of Herbert Spencer broaches what will turn out to be characteristic Jamesean themes:

the importance of religion and the passions, the variety of human responses to life, and the idea that we help to "create" the truths that we "register" (E, 21). Taking up Spencer's view that the adjustment of the organism to the environment is the basic feature of mental evolution, James charges that Spencer projects his own vision of what ought to be onto the phenomena he claims to describe. Survival, James asserts, is merely one of many interests human beings have: "The social affections, all the various forms of play, the thrilling intimations of art, the delights of philosophic contemplation, the rest of religious emotion, the joy of moral self-approbation, the charm of fancy and of wit -- some or all of these are absolutely required to make the notion of mere existence tolerable;..." (E, 13). We are all teleological creatures at base, James holds, each with his or her or own *a priori* values and categories. Spencer, then, "merely takes sides with the *telos* he happens to prefer" (E, 18).

James's fundamental empiricism is expressed in the claim that these values and categories fight it out in the course of human experience, that their conflicts "can only be solved *ambulando*, and not by any *a priori* definition." The "formula which proves to have the most massive destiny," he concludes, "will be the true one" (E, 17). Yet James wishes to defend his sense that any such formulation will be determined as much by a freely-acting human mind as by the world, a position he would later (in *Pragmatism*) call "humanism": "there belongs to mind, from its birth upward, a spontaneity, a vote. It is in the game, and not a mere looker-on; and its judgments of the should-be, its ideals, cannot be peeled off from the body of the cogitandum as if they were excrescences..." (E, 21).

"The Sentiment of Rationality" (1879, 82)

This essay was first published in *Mind* in 1879; a second part appeared in the *Princeton Review* in 1882. Both parts were used to construct the essay of this title published in *The Will to Believe and Other Essays in Popular Philosophy* (1897). Although he never quite says that rationality is a sentiment, James holds that a sentiment -- really a set of sentiments -- is a "mark" of rationality. The philosopher, James writes, will recognize the rationality of a conception "as he recognizes everything else, by certain subjective marks with which it affects him. When he gets the marks, he may know that he has got the rationality." These marks include a "strong feeling of ease, peace, rest" (WB 57), and a "feeling of the sufficiency of the present moment, of its absoluteness" (WB 58). "Fluid" thinking, whether logical or cosmological, is said to produce the sentiment, as when we learn that the "the balloon rises by the same law whereby the stone sinks" (WB 59). However, balancing the "passion for parsimony" (WB 58) such unifications satisfy is a passion for distinguishing: a "loyalty to clearness and integrity of perception, dislike of blurred outlines, of vague identifications" (WB 59). The ideal philosopher is a blend of these two passions of rationality, and James thinks that even some great philosophers go too far in one direction or another. Spinoza's unity of all things in one substance is "barren,"; and so is Hume's "'looseness and separateness' of everything..." (WB 60).

Sentiments of rationality operate not just in logic or science, but in ordinary life. When we first move into a room, for example, "we do not know what draughts may blow in upon our back, what doors may open, what forms may enter, what interesting objects may be found in cupboards and corners." These uncertainties, minor as they may be, act as "mental irritant[s]" (WB 67-8), which disappear when we know our way around the room and come to "feel at home" there. These feelings of confident

expectation, of knowing how certain things will turn out, are another form of the sentiment of rationality.

James begins the second part of his essay by considering the case when "two conceptions [are] equally fit to satisfy the logical demand" for fluency or unification. In such a case, one must consider a "practical" component of rationality: "the one which awakens the active impulses, or satisfies other aesthetic demands better than the other, will be accounted the more rational conception, and will deservedly prevail" (WB 66). James here puts the point as one of psychology -- a prediction of what will prevail -- but he also evaluates it, for it will prevail "deservedly." James rejects reductive materialism because it denies to "our most intimate powers...all relevancy in universal affairs" (WB 71), and hence fails to activate these impulses or satisfy these demands.

As in his essay on Spencer, James continues to explore the relations between the temperament that forms the philosopher's outlook and the outlook itself: "Idealism will be chosen by a man of one emotional constitution, materialism by another." James's empathetic understanding extends to both: idealism offers a sense of intimacy with the universe, the feeling that ultimately I "am all." But people of contrasting temperaments find in idealism "a narrow, close, sick-room air," leaving out an element of danger, contingency and wildness -- "the rough, harsh, sea-wave, north-wind element" (WB 75). Both the intimacy and the wildness answer to propensities, passions, and powers in human beings. Although James has his criticisms of reductive materialisms, he understands -- from the inside as it were -- some of the materialistic passion. Those with a materialistic temperament, he writes, "sicken at a life wholly constituted of intimacy," and have a desire "to escape personality, to revel in the action of forces that have no respect for our ego, to let the tides flow, even though they flow over us." The "strife" of these two forms of "mental temper," James predicts, will always be seen in philosophy (WB 76). Certainly they are always seen in the philosophy of William James.

The Principles of Psychology

James's masterwork officially follows the psychological method of introspection, defined as follows: "it means, of course, the looking into our own minds and reporting what we there discover" (PP 185). James is thinking in part of the experiments his contemporaries Wundt, Stumpf and Fechner were performing in their laboratories, which led them to results such as that "sounds are less delicately discriminated in intensity than lights" (PP 513). Although James does discuss these results in detail, many of his most important and memorable introspective observations come from his everyday experience. For example:

> The rhythm of a lost word may be there without a sound to clothe it....Everyone must know the tantalizing effect of the blank rhythm of some forgotten verse, restlessly dancing in one's mind, striving to be filled out with words (PP 244).
>
> Our father and mother, our wife and babes, are bone of our bone and flesh of our flesh. When they die, a part of our very selves is gone. If they do anything wrong, it is our shame. If they are insulted, our anger flashes forth as readily as if we stood in their place. (PP 280).

> There is an excitement during the crying fit which is not without a certain pungent pleasure of its own; but it would take a genius for felicity to discover any dash of redeeming quality in the feeling of dry and shrunken sorrow (PP, p. 1061).

> "*Will you or won't you have it so?*" is the most probing question we are ever asked; we are asked it every hour of the day, and about the largest as well as the smallest, the most theoretical as well as the most practical, things. We answer by *consents or non-consents* and not by words. What wonder that these dumb responses should seem our deepest organs of communication with the nature of things! (PP, p. 1182).

In this last quotation, James tackles a philosophical problem from a psychological perspective. Although he refrains from answering the question of whether these "responses" are in fact deep organs of communication with the nature of things -- reporting only that they seem to us to be so -- in his later writings, such as *Varieties of Religious Experience*, and *A Pluralistic Universe*, he confesses, and to some degree defends, his belief that the question should be answered affirmatively.

In the deservedly famous chapter on "The Stream of Thought" James takes himself to be offering a richer account of experience than those of traditional empiricists such as Hume. He believes relations, vague fringes, and tendencies are as experienced directly (he would later label this fact part of his "radical empiricism.") Rather than a succession of "ideas," James finds a stream, the waters of which blend; and where, because of its position in the flow, each situation is unique. Our consciousness -- or, as he prefers to call it sometimes, our "sciousness" -- , is "steeped and dyed" in the waters of sciousness or thought that surround it. Our psychic life not only has edges, it has rhythm: it is a series of transitions and resting-places, of "flights and perchings" (PP 236). We rest when we remember the name we have been searching for; and we are off again when we hear a noise that might be the baby waking from her nap.

Interest -- and its close relative, attention -- is a major component not only of James's psychology, but of the epistemology and metaphysics that seep into his discussion. A thing, James states in "The Stream of Thought," is a group of qualities "which happen practically or aesthetically to interest us, to which we therefore give substantive names.... (PP 274). And reality "*means simply relation to our emotional and active life...whatever excites and stimulates our interest is real* " (PP 924).

Our capacity for attention to one thing rather than another is for James the sign of an "*active* element in all consciousness,...a spiritual something...which seems to go out to meet these qualities and contents, whilst they seem to come in to be received by it." (PP 285). This "spiritual something" is the target of another passage from James's chapter on "Attention," where he speaks of "a star performer" or "original psychic force" which takes the form not of mere attention, but of "*the effort to attend*." According to James's revisionary account of freedom, we are mostly not free, but we achieve freedom in cases which settle, for a while, the direction or orientation of our lives. In these cases we feel the "sting and excitement of our voluntary life," and we sense that "things are really being decided..." (PP, 429). Faced with the tension between scientific determinism and our belief in our own freedom or autonomy, James

restricts the claims of science, which "must be constantly reminded that her purposes are not the only purposes, and that the order of uniform causation which she has use for, and is therefore right in postulating, may be enveloped in a wider order, on which she has no claims at all" (PP, 1179).

The Principles thus encompasses several metaphysical and methodological stances. James often writes as a scientist, as befits his education in biology and medicine. The second and third chapters are entitled "The Functions of the Brain" and "On Some General Conditions of Brain Activity." James alleges that habit, the subject of the fourth chapter, is "at bottom a physical principle" (PP 110). Yet, James presents himself -- as in his title -- as a psychologist, not as a physiologist. The method of the psychologist "first last and always" is introspection, which sometimes reveals a personal, traditionally subjective stream of thought, but which, as practiced by James, anticipates phenomenology in its pursuit of a more "pure" description of the stream of thought that does not presuppose it to be mental or material. One such passage concerns a

> child newly born in Boston, who gets a sensation from the candle-flame which lights the bedroom, or from his diaper-pin [who] does not feel either of these objects to be situated in longitude 71 W. and latitude 42 N.....The flame fills its own place, the pain fills its own place; but as yet these places are neither identified with, nor discriminated from, any other places. That comes later. For the places thus first sensibly known are elements of the child's space-world which remain with him all his life" (PP 681-2).

This passage, taking off from sensations, is rooted in James's empiricism, but it operates as a counter to traditional empiricism, for which "all our sensations at first appear to us as subjective or internal, and are afterwards and by a special act on our part ‘extradited’ or ‘projected’ so as to appear located in an outer world" (PP 678). In contrast, James's view is that the outer and inner worlds are later constructions from the original data of consciousness -- which are neither objective nor subjective. This psychological view anticipates James's late metaphysical "pure experience" account, published in *Essays in Radical Empiricism*.

Two noteworthy chapters late in *The Principles* are entitled "The Emotions" and "Will." The first sets out the theory -- also enunciated by the Danish physiologist Carl Lange -- that emotion follows, rather than causes, its bodily expression: "Common-sense says, we lose our fortune, are sorry and weep; we meet a bear, are frightened and run; we are insulted by a rival, are angry and strike. The hypothesis here to be defended says that this order of sequence is incorrect...that we feel sorry because we cry, angry because we strike, afraid because we tremble....." (PP, pp. 1065-6). The significance of this view, according to James, is that our emotions are tied in with our bodily expressions. What, he asks, would grief be "without its tears, its sobs, its suffocation of the heart, its pang in the breast-bone?" Not an emotion, James answers, for a "purely disembodied human emotion is a nonentity" (PP 1068). As Wittgenstein was to suggest, the human body may be "the best picture of the human soul" (Ludwig Wittgenstein, *Philosophical Investigations*, New York, Macmillan, 1968, p. 178).

In his chapter on "Will" James opposes the theory of his contemporary Wilhelm Wundt that there is one

special feeling -- a "feeling of innervation" -- present in all intentional action. In his survey of a range of cases, James finds that some actions involve an act of resolve or of outgoing nervous energy, but others do not. For example:

> I sit at table after dinner and find myself from time to time taking nuts or raisins out of the dish and eating them. My dinner properly is over, and in the heat of the conversation I am hardly aware of what I do; but the perception of the fruit, and the fleeting notion that I may eat it, seem fatally to bring the act about. There is certainly no express fiat here;..." (PP 1131).

The chapter on "Will" also contains striking passages that anticipate the concerns of *The Varieties of Religious Experience*: about moods, "changes of heart," and "awakenings of conscience." These, James observes, may affect the "whole scale of values of our motives and impulses (PP 1140).

The Will to Believe and Other Essays in Popular Philosophy

This popular and influential collection includes "The Sentiment of Rationality" (discussed above), and essays on "The Dilemma of Determinism," "Great Men and Their Environment" and "Is Life Worth Living?" Its most famous essay gives the collection its title, although James later wrote that he should have called the essay "the *right* to believe," indicating his justificatory intent.

In science, James notes, we can afford to await the outcome of investigation before coming to a belief. The cases of belief formation and justification to which James draws attention in "The Will to Believe" are, in contrast, "forced" -- we must come to some belief even if all the relevant evidence is not in. If I am on a mountain trail, faced with an icy ledge to cross, and do not know whether I can make it, I may be forced to consider the question whether I can or should believe that I can cross the ledge. This is a "momentous" question: if I am wrong I may fall to my death, and if I believe rightly that I can cross the ledge, my holding of the belief may itself contribute to my success. In such a case, James asserts, I have the "right to believe" -- precisely because such a belief may help bring about the fact believed in. This is a case "where a fact cannot come at all unless a preliminary faith exists in its coming" (WB 25).

James applies his analysis to religious belief, particularly to the possible case in which one's salvation depends on believing in God in advance of any proof that God exists. In such a case the belief may be justified by the outcome to which having the belief leads. James also takes his analysis outside of the religious domain, to a wide range of secular human life:

> A social organism of any sort is what it is because each member proceeds to his own duty with a trust that the other members will simultaneously do theirs.... A government, an army, a commercial system, a ship, a college, an athletic team, all exist on this condition, without which not only is nothing achieved, but nothing is even attempted (WB, 24).

James tries to justify the systems of "trust" on which society's beliefs and actions are based. Yet at the same time there is an intensely personal, even existential, tone to his essay, epitomized by James's appeal near the end to "respect one another's mental freedom," and by his concluding citation of Fitz James Stephen's statement that "‘In all important transactions of life we have to take a leap in the dark....’"(WB 31).

Another essay in the collection, "Reflex Action and Theism," attempts a reconciliation of science and religion. By "reflex action" James understands the biological picture of the organism as responding to sensations with a series of actions. Human beings and other higher animals have evolved a theoretical or thinking stage between the sensation and the action, and it is here that God comes up, at least for human beings. James holds that the thought of God is a natural human response to the universe, regardless of whether we can prove that God exists. God will be, as James puts it, the "centre of gravity of all attempts to solve the riddle of life" (WB, 116). James ends the essay by advocating a "theism" that posits "an ultimate opacity in things, a dimension of being which escapes our theoretic control" (WB, 143).

The Will to Believe also contains James's most developed account of morality, "The Moral Philosopher and the Moral Life." Morality for James rests on sentience -- without it there are no moral claims and no moral obligations. But once sentience exists, a claim is made, and morality gets "a foothold in the universe" (WB 198). Although James insists that there is no common essence to morality, he does find a guiding principle for ethical philosophy in the principle that we "satisfy at all times as many demands as we can" (WB, 205). This satisfaction is to be arrived at by working towards a "richer universe...the good which seems most organizable, most fit to enter into complex combinations, most apt to be a member of a more inclusive whole" (WB, 210). We arrive at laws and moral formulations by a kind of "experiment," James holds. (WB, 206). By such experiments, we have liberated ourselves for the most part from slavery and "arbitrary royal power" (WB, 205). But there is nothing final about the results: "as our present laws and customs have fought and conquered other past ones, so they will in their turn be overthrown by any newly discovered order which will hush up the complaints that they still give rise to, without producing others louder still" (WB, 206).

The Varieties of Religious Experience

Like *The Principles of Psychology*, *Varieties* is "A Study in Human Nature," as its subtitle says. But at some five hundred pages it is only half the length of *The Principles of Psychology*, befitting its more restricted, if still immense, scope. For James studies that part of human nature that is, or is related to, religious experience. His interest is not in religious institutions, ritual, or, even for the most part, religious ideas, but in "the feelings, acts, and experiences of individual men in their solitude, so far as they apprehend themselves to stand in relation to whatever they may consider the divine" (V, 31).

James sets out a central distinction of the book in early chapters on "The Religion of Healthy-Mindedness" and "The Sick Soul." The healthy-minded religious person -- Walt Whitman is one of James's main examples -- has a deep sense of "the goodness of life," (79) and a soul of "sky-blue tint"

(80). Healthy-mindedness can be involuntary, just natural to someone, but often comes in more willful forms. Liberal Christianity, for example, represents the triumph of a resolute devotion to healthy-mindedness over a morbid "old hell-fire theology" (91). James also cites the "mind-cure movement" of Mary Baker Eddy, for whom "evil is simply a lie, and any one who mentions it is a liar" (107). This remark allows us to draw the contrast with the religion of "The Sick Soul," for whom evil cannot be eliminated. From the perspective of the sick soul, "radical evil gets its innings" (163). No matter how secure one may feel, the sick soul finds that "[u]nsuspectedly from the bottom of every fountain of pleasure, as the old poet said, something bitter rises up: a touch of nausea, a falling dead of the delight, a whiff of melancholy...." These states are not simply unpleasant sensations, for they bring "a feeling of coming from a deeper region and often have an appalling convincingness" (136). James's main examples here are Leo Tolstoy's "My Confession," John Bunyan's autobiography, and a report of terrifying "dread" -- allegedly from a French correspondent but actually from James himself. Some sick souls never get well, while others recover or even triumph: these are "twice-born." In chapters on "The Divided Self, and the Process of Its Unification" and on "Conversion," James discusses St. Augustine, Henry Alline, Bunyan, Tolstoy, and a range of popular evangelists, focusing on what he calls "the state of assurance" (241) they achieve. Central to this state is "the loss of all the worry, the sense that all is ultimately well with one, the peace, the harmony, the *willingness to be*, even though the outer conditions should remain the same" (248).

Varieties' classic chapter on "Mysticism" offers "four marks which, when an experience has them, may justify us in calling it mystical..." (380). The first is ineffability: "it defies expression...its quality must be directly experienced; it cannot be imparted or transferred to others." Second is a "noetic quality": mystical states present themselves as states of knowledge. Thirdly, mystical states are transient; and, fourth, subjects are passive with respect to them: they cannot control their coming and going. Are these states, James ends the chapter by asking, "windows through which the mind looks out upon a more extensive and inclusive world[?]" (428).

In chapters entitled "Philosophy" -- devoted in large part to pragmatism -- and "Conclusions," James finds that religious experience is on the whole useful, even "amongst the most important biological functions of mankind," but he concedes that this does not make it true. James articulates his own belief -- which he does not claim to prove -- that religious experiences connect us with a greater, or further, reality not accessible in our normal cognitive relations to the world: "The further limits of our being plunge, it seems to me, into an altogether other dimension of existence from the sensible and merely ‘understandable’ world" (515).

Late Writings

Pragmatism (1907)

James first announced his commitment to pragmatism in a lecture given at Berkeley in 1898, entitled "Philosophical Conceptions and Practical Results." Other sources for *Pragmatism* were lectures given at Wellesley College in 1905, and at the Lowell Institute and Columbia University in 1906 and 1907.

Pragmatism emerges in James's book as five things: a philosophical temperament, a theory of truth, a theory of meaning, a holistic account of knowledge, and a method of resolving philosophical disputes.

The pragmatic temperament appears in the book's opening chapter, where James classifies philosophers according to their tough-or tender-mindedness. The pragmatist is a mediator like James himself, someone with "scientific loyalty to facts" as well as "the old confidence in human values and the resultant spontaneity, whether of the religious or romantic type" (P, 17). The method of resolving disputes and the theory of meaning are on display in James's discussion of an argument about whether a man chasing a squirrel around a tree goes around the squirrel too. Taking meaning as the "conceivable effects of a practical kind the object may involve," the pragmatist philosopher finds that two "practical" meanings of "go around" are in play: either the man goes North, East, South, and West of the squirrel, or he faces first the squirrel's head, then one of his sides, then his tail, then his other side. "Make the distinction," James writes, "and there is no occasion for any further dispute."

The pragmatic theory of truth is the subject of the book's sixth (and to some degree its second) chapter. Truth, James holds, is "a species of the good," like health. Truths are goods because we can "ride" on them into the future without being unpleasantly surprised. They "lead us into useful verbal and conceptual quarters as well as directly up to useful sensible termini. They lead to consistency, stability and flowing human intercourse. They lead away from excentricity and isolation, from foiled and barren thinking" (103). James holds that truths are "*made*" (104) in the course of human experience; yet although they live for the most part "on a credit system" in that they are not currently being verified by most of those who have them, "beliefs verified concretely by *somebody* are the posts of the whole superstructure" (P, 100).

James's chapter on "Pragmatism and Humanism" sets out James's voluntaristic epistemology. "We carve out everything," he states, "just as we carve out constellations, to serve our human purposes" (P, 100). Nevertheless, he recognizes "resisting factors in every experience of truth-making" (P, 117), including not only our present sensations or experiences but the whole body of our prior beliefs. James holds neither that we create our truths out of nothing, nor that truth is entirely independent of humanity. He embraces "the humanistic principle: you can't weed out the human contribution" (P, 122). *Pragmatism's* final chapter on "Pragmatism and Religion" follows James's line in *Varieties* in attacking "transcendental absolutism" for its unverifiable account of God, and in defending a "pluralistic and moralistic religion" (144) based on human experience. "On pragmatistic principles," James writes, "if the hypothesis of God works satisfactorily in the widest sense of the word, it is true" (143).

A Pluralistic Universe (1909)

Originally delivered in Oxford as a set of lectures "On the Present Situation in Philosophy," James's book begin with a discussion of philosophic temperament. He condemns the "over-technicality and consequent dreariness of the younger disciples at our American universities..." (PU 13), and holds that a philosopher's "vision" is "the important thing" about him (PU 3). Passing from critical discussions of Royce's idealism and the "vicious intellectualism" of Hegel, James comes, in chapters four through six,

to philosophers whose vision he admires. He praises Gustav Fechner for holding that "the whole universe in its different spans and wave-lengths, exclusions and developments, is everywhere alive and conscious" (PU, 70), and he seeks to refine and justify Fechner's idea that separate human, animal and vegetable consciousnesses meet or merge in a "consciousness of still wider scope" (72). James employs Henri Bergson's critique of "intellectualism" in this project, for Bergson shows that the "concrete pulses of experience appear pent in by no such definite limits as our conceptual substitutes are confined by. They run into one another continuously and seem to interpenetrate" (PU 127). James concludes by embracing a position that he had more tentatively set forth in *The Varieties of Religious Experience*: that religious experiences "point with reasonable probability to the continuity of our consciousness with a wider spiritual environment from which the ordinary prudential man (who is the only man that scientific psychology, so called, takes cognizance of) is shut off" (PU, 135). Whereas in *Pragmatism* James subsumes the religious within the pragmatic (as yet another way of successfully making one's way through the world), in *A Pluralistic Universe*, James distinguishes the religious from the "prudential" or "practical."

Essays in Radical Empiricism (1912)

James's radical empiricism, which is basically an epistemological doctrine, has been confused with the metaphysical doctrine of "pure experience," largely because the latter is set forth in most of the essays collected after James's death in *Essays in Radical Empiricism*. Radical empiricism is never precisely defined in the *Essays*, being best explicated by a passage from *The Meaning of Truth* in which James states that it consists of a postulate, a statement of fact, and a conclusion. The postulate is that "the only things that shall be debatable among philosophers shall be things definable in terms drawn from experience," the fact is that relations are just as directly experienced as the things they relate, and the conclusion is that "the parts of experience hold together from next to next by relations that are themselves parts of experience" (MT, 6-7).

James's "pure experience" doctrine is the view that Bertrand Russell -- giving full credit to James in *The Analysis of Mind* -- calls "neutral monism." James holds that mind and matter are both aspects of, or structures formed from, a more fundamental stuff -- pure experience -- that (despite being called "experience") is neither mental nor physical. Pure experience, James explains, is "the immediate flux of life which furnishes the material to our later reflection with its conceptual categories... a *that* which is not yet any definite *what*, tho' ready to be all sorts of whats..." (ERE, 46). That "whats" pure experience may be include minds and bodies, people and material objects. The "what" of pure experience depends not on a fundamental ontological difference among experiences, but on the *relations* into which pure experiences enter. Certain sequences of pure experiences constitute physical objects, and others constitute persons; but one pure experience (say the perception of a chair) may be part both of the sequence constituting the chair and of the sequence constituting a person.

Panpsychism

Panpsychism is the doctrine that mind is a fundamental feature of the world which exists throughout the universe. Unsurprisingly, each of the key terms, "mind", "fundamental" and "throughout the universe" is subject to a variety of interpretations by panpsychists, leading to a range of possible philosophical positions. For example, an important distinction is that between conscious and unconscious mental states, and appeal to it allows a panpsychism which asserts the ubiquity of the mental while denying that consciousness is similarly widespread. Interpretations of "fundamental" range from the inexplicability of mentality in other, and non-mentalistic, terms to the idealist view that in some sense everything that exists is, and is only, a mental entity. And, although the omnipresence of the mental would seem to be the hallmark feature of panpsychism, there have been versions of the doctrine that make mind a relatively rare and exceptional feature of the universe.

Against the backdrop of our immense scientific knowledge of the physical world, and the corresponding widespread desire to explain everything ultimately in physical terms, panpsychism has come to seem an implausible view. Nonetheless, the doctrine retains some attractive and interesting features. The recalcitrance of the mind, and especially consciousness, to fit smoothly into the scientific picture recommends our consideration of them.

1. Panpsychism and the Scientific World View

It is salutary to remember that not so very long ago anti-physicalism was orthodox philosophical opinion. The nature of mind or consciousness was believed to be entirely distinct from physical nature. It was sometimes allowed, by Cartesian dualists, that mind interacted with the physical world causally under very rare conditions, but the mode of interaction was impossible to understand and seemed to conflict with elementary principles of physics. These worries led to such bizarre views as Malebranche's occasionalism, in which God had to intervene between volition and action, between stimulus and sensation. A yet more extreme position, idealism, which became widespread in the nineteenth century and retained much support well into the twentieth, held that mind stood as the sole ontological foundation of reality, supporting a physical world conceived of as entirely constructed -- somehow -- out of mental phenomena. Such positions have lost much of their philosophical attractiveness and there can be little doubt that the primary reason for this radical change of philosophical opinion is that a principled separation of mind and matter precludes any deep integration of mind with the ever expanding and ever more powerful scientific picture of the physical world. For most philosophers the mind-body problem has become this problem of integration and a plethora of theories, which can be gathered together under the title of physicalism, have arisen in the attempt at its solution.

Broadly speaking, there are, at bottom, only two positions that can promise the desired integration: panpsychism and emergentism. If one believes that the most fundamental physical entities (quarks, leptons, bosons, or whatever physics will ultimately settle upon) are devoid of any mental attributes, and if one also believes that some systems of these entities, such as human brains, *do* possess mental attributes, one is espousing some kind of doctrine of the *emergence* of mind. All the currently popular physicalist theories (such as behaviorism, central state identity theories, functionalism) are theories which attempt to provide an account of how the mental emerges from the physical. Other, more radical, forms of emergentism are possible. These are theories that deny that there is any explanatory account of how emergence works: it is a brute fact of natural law that certain configurations of physical entities underpin certain mental states. This fact is, or has to be accepted, as Samuel Alexander said, with "natural piety". Of course, an inexplicable or brute emergence is still a form of emergence. It is possible to mark the distinction between the forms of emergence in terms of the *explanatory* role of the mental. Modern materialists do not regard the emergent features of the mind as either ontologically or explanatorily fundamental. The more radical emergentists would regard mind as explanatorily fundamental, but not ontologically basic in the sense that material conditions (or in general some system of non-mentalistic conditions) are required for the existence of mental features. The panpsychist naturally regards mind as both explanatorily and ontologically fundamental in the sense just mentioned.

The panpsychist alternative disputes the intelligibility of emergence whether based on the claim that the nature of emergence is simply inexplicable or the claim that the mental can be reduced to a set of relations amongst purely physical entities, and thus must opt instead for the attribution of mentalistic properties to the physically fundamental entities.[1]

It always remains possible to give up the job of integrating mind into our scientific picture of the physical world in favor of accepting some more or less remote relation between independent domains of matter and mind. Cartesian dualism can be seen as involving such a refusal which in the case of Descartes was

entirely self-conscious. But integrators seem to be stuck with the dilemma of emergence versus panpsychism. By and large, the twentieth century witnessed the victory of emergentism, articulated in a bewildering, and still expanding, variety of forms.

Since panpsychism is, by definition, the doctrine that *mind*, in some sense of the term, is *everywhere*, in some sense of that term, it is worth mentioning a complication which is a possible source of confusion at the outset. There have been some panpsychists who, while being much more liberal than most in their willingness to ascribe mind, seem to have been unwilling to extend mind right down into the roots of the world. Both Gustav Fechner (1801-1887) and Josiah Royce (1855-1916) developed panpsychist accounts of nature that did not necessarily attribute mental properties to the ultimate constituents of mentalistic "systems". It would seem to be intuitively clear that if one does not place mind at the very foundation, and in fact regards mentality to be a feature of systems of non-mentalistic entities, then one is an emergentist. Crudely put, someone who believes that amoebas have experiences, but that quarks and electrons, which ultimately constitute amoebas, do not is no panpsychist. However, this simplifying view contains an implicit assumption about the nature of the fundamental physical constituents of the world, namely that the unobservable and hypothetical entities postulated by physics are entirely real and are indeed the ontological foundation of the world. In the nineteenth century, the time of panpsychism's greatest flourishing, this was a rather more daring assumption than it is today. Furthermore, underlying metaphysical assumptions, in particular various forms of idealism, can provide an overarching argument for panpsychism, and Royce (among many other panpsychists of the nineteenth century, if indeed not most thinkers of the period) was an idealist. Fechner's panpsychism was also distinctive in its endorsement of a "world-soul" or "world-mind" of which everything is a part (there are obvious echoes of Spinoza in such a view). This rather top-down view of the place of mind in the world does seem to be a legitimate sort of panpsychism, and it is one that does not require that everything in the world be itself enminded. Nonetheless, without a basis in an explicitly idealist philosophy, it leaves entirely open the question of how the word-soul comes into being. If, for example, the world-mind is conditioned by the structure of its non-mentalistic parts we would seem to be returned to some form of emergentism. In any case, the arguments of such "synechological" panpsychists (as Hartshorne (1950) labels them in contrast with "atomistic" or "monadological" panpsychists) are arguments for panpsychism in general and can be examined as such.

Panpsychism's assertion that mind suffuses the universe presents a fundamental and sharp contrast with its basic rival, emergentism, which asserts that mind appears only at certain times, in certain places under certain -- probably very special and very rare -- conditions. But trying to explicate a little more precisely the key terms of this vague characterization of panpsychism results in several different versions of it. A cardinal distinction within the realm of the mind, though one that still carries more than a whiff of controversy, is that between conscious and unconscious mental states, and thus we could wonder whether panpsychism claims that consciousness is everywhere or merely that some unconscious form of mentality (often labelled *proto-mentality*) lurks throughout the universe. With regard to the ubiquity of the mental, we might wonder whether every *thing* has a mind (or associated mental attributes) or whether there is, even from within a panpsychist view of the world, a viable distinction between things with minds and things lacking minds (as we have seen, the world-mind form of panpsychism may have the resources to fund such a distinction). We might go so far as to wonder whether mind is to be thought of as some kind

of *field-like* entity or in analogy with something as fundamental as energy[2], spread out over the universe and not connected directly with or dependent upon any particular things. Although seldom clearly distinguished, the history of panpsychism reveals that all of these variants have been tried out. So before turning to the virtues and vices of panpsychism, let's look to its past.

2. Early History of Panpsychism

Panpsychism seems to be such an ancient doctrine that its origins long precede any records of systematic philosophy. Some form of animism, which, insofar as it is any kind of *doctrine* at all, is very closely related to panpsychism, seems to be an almost universal feature of pre-literate societies, and studies of human development suggest that children pass through an animist phase, in which mental states are attributed to a wide variety of objects quite naturally (see Piaget 1929).[3] It is tempting to speculate that the basic idea of panpsychism arose in what is a common process of explanatory extension based upon the existence of what is nowadays called "folk psychology". It would have been difficult for our ancestors, in the face of a perplexing and complex world, to resist applying one of the few systematic, and highly successful, modes of explanation in their possession.

In any event, clear indications of panpsychist doctrines are evident in early Greek thought. One of the first presocratic philosophers of ancient Greece, Thales (c. 624-545 BC) deployed an analogical argument for the attribution of mind that tends towards panpsychism. The argument depends upon the idea that enminded beings are self-movers. Thales notes that magnets and, under certain circumstances, amber, can move themselves and concludes that they therefore possess minds. It is claimed that Thales went much beyond such particular attributions and endorsed a true panpsychism and pantheism. For example, as reported by Barnes (1982, pp. 96-7), Diogenes claimed that Thales believed that "the universe is alive and full of spirits" but this remark is derived from an earlier claim of Aristotle: "some say a soul is mingled in the whole universe -- which is perhaps why Thales thought that everything is full of gods". While Barnes disputes the pantheistic reading of Thales, he allows that Thales believed in the "ubiquity of animation" and hence by the above argument accepted a true panpsychism.[4]

Of greater interest is the role of ancient panpsychism in the much wider debate between panpsychism and emergentism. This basic conflict is not merely a reflection of a problem about the mind's place in the world but rather represents a fundamental distinction within our schemes for understanding the world. We like to break the world down into bits and pieces, and then face the problem of retrieving the explanatory target properties from the simpler properties of the bits. This mode of explanation began to be codified with the Presocratics who to their everlasting credit strove to produce comprehensive and refreshingly naturalistic accounts of the world. Their accounts are obscure and less than rigorously scientific, and littered with oracular pronouncements notoriously difficult to interpret, but they nonetheless do mark the beginning of the attempt to give a scientific account of the world.

The Presocratics immediately recognized the basic dilemma: either mind (or, more generally, whatever the apparently "macroscopic", "high-level", or non-fundamental property at issue) is an elemental feature of the world or it somehow emerges from, or is conditioned by, such features. If one opts for emergence,

it is incumbent upon one to at least sketch the means by which new features emerge. If one opts for panpsychism (thus broadly construed for now) then one must account for the all too obviously apparent total *lack* of certain features at the fundamental level. For example, Anaxagoras (c. 500-425 BC) flatly denied that emergence was possible and instead advanced the view that "everything is in everything". Anaxagoras explained the obvious contrary appearance by a "principle of dominance and latency" (see Mourelatos 1986) which asserted that some qualities were dominant in their contribution to the behavior and appearance of things. However, Anaxagoras's views on mind are complex since he apparently regarded mind as uniquely *not* containing any measure of other things and thus not fully complying with his mixing principles. Perhaps this can be interpreted as the assertion that mind is ontologically fundamental in a special way; Anaxagoras did seem to believe that everything has some portion of mind in it while refraining from the assertion that everything has a mind (even this is controversial, see Barnes 1982, p. 405 ff.).

On the other hand, Empedocles, an almost exact contemporary of Anaxagoras, favored an emergentist account based upon the famous doctrine of the four elements: earth, air, fire and water. All qualities were to be explicated in terms of ratios of these elements. The overall distribution of the elements, which were themselves eternal and unchangeable, was controlled by "love and strife", whose operations are curiously reminiscent of some doctrines of modern thermodynamics, in a grand cyclically dynamic universe.[5] The purest form of emergentism was propounded by the famed atomist Democritus (c. 460-370 BC). His principle of emergence was based upon the possibility of multi-shaped atoms "interlocking" to form an infinity of more complex shapes. But Democritus, in a way echoing Anaxagoras, had to admit that the *qualities* of experience (what we nowadays called "qualia") could not be accounted for in this way and chose, ultimately unsatisfactorily, to relegate them to non-existence: "sweet exists by convention, bitter by convention, in truth only atoms and the void". Although Democritus provides a remarkable anticipation of the modern doctrine of eliminativist materialism, we sorely miss his account of how *conventions* themselves -- the consciously agreed upon means of common reference -- emerge from the dancing atoms. Thus the core difficulty of the problem of consciousness remains unresolved.

What is striking about these early struggles about the proper "form" of a scientific understanding of the world, is that the mind and particularly consciousness keep rising as special problems. It is sometimes said that the mind-body problem is not an ancient philosophical worry (see Matson 1966), but it does seem that the problem of consciousness was vexing philosophers 2500 years ago, and in a form redolent of contemporary worries. Also critically important is the way that the problem of consciousness, and its origin, inescapably arises within the context of developing an integrated scientific view of the world.

3. Modern history of panpsychism

It is this that explains the lack of interest in panpsychism, emergentism etc. that sets in after the Presocratics and lasts until the scientific revolution of the seventeenth century with its renewed interest in comprehensive naturalistic accounts of the world. The modern "mechanistic" picture of the world inaugurated by Galileo, Descartes and Newton put the problem of the mind at center stage while paradoxically sweeping it under the rug.[6] The whole problem-space was severely distorted by what was

virtually a stipulated separation of matter from mind, so that what could have been merely a useful conceptual distinction was transformed into an ontological gulf. Thus, everything that could not be accounted for in terms of the interactions of simple material components was conveniently labelled a "secondary quality" inhabiting not the "real" world but merely the conscious mind. For instance, in a maneuver reminiscent of Democritus, colors were banished from the world of matter, replaced with the "causal powers" of physical things to produce "in the mind" the experience we call color. Thus the world was made safe for physics.

But the problem of the relation of the physical world to conscious minds was unavoidable and became ever more pressing. As Newton himself drolly pointed out in a letter to Henry Oldenburg: " ... to determine by what modes or actions light produceth in our minds the phantasm of colour is not so easie." One option was simply to give up - remove the mind from the expanding scientific picture of the world, and such was the motivation for René Descartes's infamous dualism of mind and body. But this leaves us with an untidy, perhaps incoherent, and certainly disintegrated view of the world. Another approach was to question the underlying definitional move of the scientific revolution, which was to *stipulate* that science was to study a "purely physical" world, voided of mentality by fiat. For one can wonder whether there is such a world. This question exacts its own price, however, which is our familiar dilemma, to which many thinkers responded with an endorsement of panpsychism.

Baruch Spinoza (1632-77) and Gottfried Wilhelm Leibniz (1646-1716) provide examples of two distinct and formatively important versions of panpsychism. Spinoza regarded both mind and matter as simply aspects (or attributes) of the eternal, infinite and unique *substance* he identified with God Himself. In the illustrative scholium to proposition seven of book two of the *Ethics* (1677/1985) Spinoza writes: "a circle existing in nature and the idea of the existing circle, which is also in God, are one and the same thing ... therefore, whether we conceive nature under the attribute of Extension, or under the attribute of Thought ... we shall find one and the same order, *or* one and the same connection of causes ...". We might say that, for Spinoza, physical science is a way of studying the psychology of God. There is nothing in nature that does not have a mental aspect -- the proper appreciation of matter itself reveals it to be the other side of a mentalistic coin.

Leibniz's view is sometimes caricatured as: Spinoza with infinitely many rather than just one substance. These substances Leibniz called *monads* (see Leibniz 1714/1989). Since they are true substances, and hence can exist independently of any other thing, and since they are absolutely *simple*, they cannot interact with each other in any way (nonetheless they are created by God, who is one of them -- here Spinoza seems rather more consistent than Leibniz). Yet each monad carries within it complete information about the entire universe. What we call space and time are in reality sets of relations amongst these monads (or, better, the information which they contain) which are in themselves radically non-spatial and perhaps even non-temporal (Leibniz's vision of space and time emerging from some more elementary systems of relations has always been tempting, if hard to fathom, and now fuels some of the most advanced physics on the planet).

Leibniz's monads are fundamentally to be conceived mentalistically -- they are in a way mentalistic automatons moving from one perceptual state (some conscious and some not) to another, all exactly

according to a God imposed pre-defined rule. It is highly significant for the development of later forms of panpsychism that Leibniz could find no intrinsic nature for his basic elements other than a mentalistic nature -- the only model he found adequate to describe his monads was one of perception and spontaneous activity. The physical world is, so to speak, an aspect of these perceptual states (so Leibniz's panpsychism is one that favors the mental realm, that is, it is at bottom a kind of idealism as opposed to Spinoza's "neutral monism"). What is of special interest is that unlike Spinoza, Leibniz can maintain a distinction between things that have minds or mental attributes from those that do not, despite his panpsychism. This crucial distinction hinges on the difference between a "mere aggregate" and what Leibniz sometimes calls an "organic unity" or an *organism*. Each monad represents the world -- in all its infinite detail -- from a unique point of view (both literally in the sense of having a perceptual perspective but also in terms of clarity and "significance"). Consider a heap of sand. It corresponds to a set of monads, but there is no monad which represents anything like a "point of view" of the heap. By contrast, your body also corresponds to a set of monads but one of these monads -- the so called *dominant* monad -- represents the point of view of the system which is your living body. (There presumably are also sub-unities within you, corresponding to organized and functionally unified physiological, and hence also psychological, sub-systems.) Organisms correspond to a hierarchically ordered set of monads, mere aggregates do not. This means that there is no mental aspect to heaps of sand as such, even though at the most fundamental level mind pervades the universe. In fact, for Leibniz minds are only rarely associated with physical systems and he explicitly denied that the world-system had a corresponding monad. In sharp contrast with Spinoza's views, Leibniz's universe is a mere aggregate. One last point: you might wonder why you, a monad that represents every detail of the entire universe, seem so relatively ignorant. The answer depends upon another important aspect of the conception of mentality. Leibniz allows that there are unconscious mental states. In fact, almost all mental states are unconscious and low-level monads never aspire to consciousness (or what Leibniz calls *apperception*). You are aware, of course, only of your conscious mental states and these represent a literally infinitesimal fraction of the life of your mind, the most of which is composed of consciously imperceptible *petite perceptions* (it is galling to think that the answers to such questions as whether there are advanced civilizations in the Andromeda galaxy lie hidden within each of our minds, but there it is).

The growth of idealist philosophy through the eighteenth and nineteenth centuries meant that panpsychism became, in effect, the default philosophy, but of course with a decided bias resulting from the positioning of mentality as the primary component of reality. However, this had little effect upon science (though it may well have contributed to the growth of positivism and "radical empiricism" in the *philosophy* of science) which throughout this period continued to rapidly expand in every direction, laying the groundwork for the overthrow of a philosophy-based mentalistic metaphysics with the physics-based scientific/materialistic metaphysical structure within which we still reside today.

The nineteenth century was the heyday of panpsychism. Even a partial list of panpsychists of that period reveals how many of the best minds of the time gravitated towards this doctrine. Prominent exponents of distinctive forms of panpsychism include Gustav Fechner, one of the founders of scientific psychology, Wilhelm Wundt (1832-1920), another famous early psychologist who established the first psychological research laboratory, Rudolf Hermann Lotze (1817-1881), a polymath who also figured in the creation of psychology as an empirical science, William James (1842-1910), the brilliant American philosopher and

psychologist who co-founded the philosophy of pragmatism, Josiah Royce (1855-1916), famed teacher and defender of a monistic idealism (in this respect, Royce had a philosophical role in America similar to that of F. H. Bradley in Britain), and William Clifford (1845-1879), a tragically short lived mathematical and philosophical genius whose work on of the nature of space and time prefigured Einstein's general relativity.

Other notable panpsychist thinkers of this period include Arthur Schopenhauer (1788-1860), who held the curious dual doctrine that everything is conscious, but that *not* everything is alive, Friedrich Paulsen (1846-1908), a student of Fechner's who extended his teacher's version of panpsychism, Morton Prince (1854-1929), psychologist and physician who advocated a panpsychism which emphasized that it is matter that must be "psychologized" or imbued with mentalistic attributes (Prince regarded this as a form of materialism and there are affinities here with some recent views of Galen Strawson as we shall see below). Also to be mentioned are Eduard von Hartmann (1842-1906) who extended his famous doctrine of the unconscious down to the level of atoms, Ferdinand C. S. Schiller (1864-1937) who provided a pragmatist defense of panpsychism as a doctrine which by various analogical arguments yields otherwise unattainable insights into nature and Ernst Häckel (1834-1919), an early and avid proponent of Darwinism in Germany who Clifford credits with the evolutionary continuity argument for panpsychism (for which see below) and Häckel was certainly willing to ascribe mental properties to living cells.

Royce and Lotze represent what may be called "idealist panpsychism". That is, the primary motivation for the ascription of mental attributes to matter is that matter is, in essence, a "form" of mind and thus panpsychism is a kind of *theorem* which follows from this more fundamental philosophical view. Royce believed that reality was a "world self", a conscious being that comprised absolutely everything and of which we, as well as everything else of course, were but parts. But Royce's panpsychism was of the synechological variety. Although every thing participates in the conscious life of the world self, not every "object" which one might nominate within the world of experience need itself be conscious, for these things are but thoughts of the world self and do not necessarily correspond to a being (or a sub-being) with its own mental life or consciousness. Yet some aspects of the world self do have a conscious life of their own. We are obvious examples, but Royce also believed that the range of such conscious beings went far beyond what we normally allow. Planets, stars and galaxies and even *species* are themselves conscious beings.[7] To the complaint that such things exhibit no sign of conscious life or thought, Royce had an interesting reply that raises intriguing philosophical issues. The reply was that the time scale of a conscious mind could vary tremendously -- the scale of the processes of consciousness in a galaxy are billions of time slower than the scale of human conscious processes (and mayhap the consciousness of subatomic particles, if they be conscious at all, runs billions of times faster).

Fechner, Wundt and perhaps James are "parallelist panpsychists". Their metaphysics endorses a thorough going, Spinozistic, parallelism between mind and matter, so that every physical entity has mental attributes, and vice versa. In fact, it was this metaphysical parallelism that suggested to Fechner the idea that there should be a lawful relation between the mental and the physical, which led to the birth of psycho-physics and the discovery of his famous law relating the strength of a sensation, S, to the strength of the physical stimulus, P: $S = k \log(P)$ (still one of the very few psycho-physical laws with any claim to validity). This is an interesting, if minor, illustration of the general point that scientific advance is often

contingent upon more or less explicit background metaphysical views. Although a clear scientific thinker Fechner was given to some rather mystical flights of fancy in defense of what he called the "day-view" (that is, the vibrant, open, panpsychist understanding of the world) as opposed to the dark and dead "night-view" of materialism. In the rather curiously entitled *The Little Book of Life After Death*, which was highly popular, boasted an introduction by no less than William James, and was last reprinted in 1977, Fechner asserts that "the plant thinks it is in its place ... to play with beetles and bees". Charles Hartshorne, a panpsychist himself, drily remarks of Fechner's ascription of consciousness to plants: "whatever can be said for this view must, it seems, have been said by Fechner" (1950, p. 447).

As mentioned above, Fechner's panpsychism is usually regarded to be of the synechological variety which withholds mental attributes from some of the simple constituents of larger, enminded systems (up to and including the world-soul itself). This view of Fechner stems from the extreme reliance Fechner placed upon analogical arguments for the existence of mental qualities, and which he regarded as the sole ground for the attribution of mind to anything other than oneself. Thus plants are like animals which are *asleep*, but not thereby mindless nor even unconscious, insofar as they possess no less than animals a complex set of teleological mechanisms serving their perseverance. Fechner was much taken to task for his failure to endorse a thorough going panpsychism by, among others, Lotze, who wrote (referring to Fechner's (1848) *Nanna, or On the Mental Life of the Plants*) "one cannot search for the mind arbitrarily in the plants, the darlings of our fantasy, and remain satisfied with the existence of dead matter in the rocks" (Lotze 1852, p. 133). This is worth mentioning since there is evidence that Fechner, in *Zend-Avista* (first published in 1851), did take the seemingly logical step of extending his panpsychism to all of nature, in line with the dual aspect metaphysics which he officially advocated (see Woodward 1972, from which the above translation).

William James's panpsychism grew out of his "neutral monism" -- the view that reality is *neither* mental nor physical but has a distinct, and seemingly intrinsically mysterious, basic character which can be regarded as either mental or physical from certain viewpoints. To the extent that a neutral monism can be regarded as a dual-aspect view (as in Spinoza's philosophy), it might be regarded as a kind of panpsychism in its own right, but James's view developed beyond this, to incorporate mind like elements into the basic structure of reality. In a notebook of 1909 he wrote: "the constitution of reality which I am making for is of the psychic type" (see Cooper 1990). James's commitment to panpsychism remains somewhat controversial, since he also advanced a cogent set of objections against a version of the view, which he somewhat derisively labelled the "mind dust" theory, in chapter six of *The Principles of Psychology* (1890/1950). But in the end his commitment is quite clear (see James (1911), and for an excellent analysis of James's views on mind see Cooper (1990)).

The most significant development and defense of a panpsychist philosophy in the twentieth century was undoubtably that of Alfred North Whitehead (1861-1847). Exploration of the details of Whitehead's philosophy would require an article of its own, and would be fraught with interpretive difficulties in any case since Whitehead's own presentation is forbiddingly complex, full of idiosyncratic technical terms and sometimes of dubious intelligibility. But roughly speaking Whitehead proposed a radical reform of our conception of the fundamental nature of the world, placing *events* (or items that are more event-like than thing-like) and the ongoing *processes* of their creation and extinction as the core feature of the

world, rather than the traditional triad of matter, space and time. His panpsychism arises from the idea that the elementary events that make up the world (which he called *occasions*) partake of mentality in some -- often extremely attenuated -- sense, metaphorically expressed in terms of the mentalistic notions of creativity, spontaneity and perception. The echoes of Leibniz are not accidental here, and Whitehead also has a form of Leibniz's distinction between *unities* and mere *aggregates*, which he explains in these terms: "... in bodies that are obviously living, a coordination has been achieved that raises into prominence some functions inherent in the ultimate occasions. For lifeless matter these functionings thwart each other, and average out so as to produce a negligible total effect. In the case of living bodies the coordination intervenes, and the average effect of these intimate functionings has to be taken into account" (1933, p. 207; lest it seem that Whitehead is only discussing *life*, he is clear that this depends upon a sort of mental functioning). Unavoidably, if perhaps unfortunately, Whitehead's panpsychism stands or falls with his entire metaphysical system which entails a more radical revision of our current scientifically based picture of the world than even panpsychism necessitates. In very general terms, Whitehead's panpsychism faces the same objections as any other version, and stems from the same basic anti-emergentist intuition (for a clear introduction to, and defense of, Whitehead's panpsychism see Griffin 1998; another interpretation, and pantheistic reworking, can be found in the writings of Charles Hartshorne (1897-2000), for example, in Hartshorne 1972).

With his emphasis on the vitality and spontaneity of nature, Whitehead represents a culmination of nineteenth century panpsychist thinking, and probably not coincidentally its presentation was pretty much simultaneous with the culminating development of a robust and serious emergentism (as worked out by, for example, C. Lloyd Morgan (1852-1936) and C. D. Broad (1887-1971)). It may have seemed that, for a moment, the ground was prepared for another great battle between the two basic conflicting ideas about mind's place in the natural world. But history moved in another direction. Big science took center stage, and metaphysics became a bit player in a new kind of philosophical drama. The kind of radical emergentism espoused by thinkers such as Broad was doomed by the huge technological advances and theoretical successes of physical science, in particular quantum mechanics' victory in explaining how chemical complexity arises from purely physical principles, along with the rise of a logical positivist philosophy that derided any philosophical idea that was not cleanly rooted in empirical science. But all this also had the predictable effect of relegating panpsychism, which also required a philosophical extension of scientific belief, to the limbo of unwarranted philosophical intercession into domains beyond its expertise.

Thus for some fifty years after the 1929 publication of Whitehead's panpsychist *Process and Reality* and the 1925 publication of C. D. Broad's emergentist *Mind and Its Place in Nature* there was relatively little interest in either doctrine. There are few explicit defenders of panpsychism at the present time. The two most prominent are Timothy Sprigge and David Griffin, who also represent two of the main versions of panpsychism. Sprigge, in *A Vindication of Absolute Idealism* (1983), defends an idealist based panpsychism somewhat akin to that of Royce, while Griffin, in *Unsnarling the World Knot* (1998), espouses an atomistic panpsychism in the form of an explicit interpretation, extension and defense of Whitehead's version of the doctrine. Although not providing full scale defences of panpsychism, several other writers have recently approached the problem of consciousness in ways sympathetic to panpsychism. See for example chapter eight of Chalmers (1996), or the articles by Piet Hut and Roger

Shepard, Gregg Rosenberg, and William Seager, all in Shear (1997).

The current burst of scientific and philosophical studies of mind sparked by the "cognitive revolution" has rekindled debate about the perennial dilemma of emergentism versus panpsychism. The recently renewed and once again influential claim of some philosophers, especially David Chalmers, that the explanation of consciousness presents a uniquely difficult problem for science has forced the reexamination of the metaphysical foundations of the scientific world view (see *The Conscious Mind* 1996). Chalmers calls this problem the "hard problem of consciousness"; it is also sometimes called the "explanatory gap" or the "generation problem". The key difficulty is how to explain in naturalistic terms the generation of consciousness by "mere matter". Once again it seems imperative to decide whether and how mind *emerges* upon, or exists only under, some specifiable and non-universal natural and non-mentalistic conditions or whether mind itself forms a part of the fundamental structure of the world, perhaps in some of the ways panpsychists have suggested.

4. Arguments For Panpsychism

In an excellent article on panpsychism and its history, Paul Edwards (1967) divided the arguments for panpsychism into two broad categories: genetic and analogical. The division is incomplete but makes a fine start. Genetic arguments assert that the best account of the genesis of mind lies in panpsychism; the analogical arguments seek to find analogies between clearly enminded entities and the rest of nature which are strong enough to warrant the extension of mental attributes throughout nature.

4.1 Genetic Arguments

There exist both *a priori* and empirical genetic arguments. The claim that emergence is strictly impossible has a metaphysical root in the ancient dictum "ex nihlio, nihil fit" to which Wundt, for example, explicitly appealed (see Wundt 1892/1894, p. 443). A much more recent version of this argument can be found in Nagel's article "Panpsychism" (1979). Nagel explicitly links panpsychism to a necessary failure of emergentism, namely that emergentism cannot rise to the status of a *metaphysical* relation. Nagel says: "there are no truly emergent properties of complex systems. All properties of complex systems that are not relations between it and something else derive from the properties of its constituents and their effects on each other when so combined" (p. 182). Thus the only coherent form of emergentism is an epistemological doctrine about the limits of our understanding of the behavior of complex systems. The link to panpsychism appears with Nagel's denial of reductionism, which precludes simply identifying mental properties with complex physical properties. Then, since, as Nagel says, we can build an enminded system out of "any matter", mind must be associated with matter in general and in its most fundamental forms (whatever these may be as eventually revealed by physics).[8] The argument appears to suffer from the lack of a clear proof that a more radical form of emergentism than the epistemological variety countenanced by Nagel is impossible. Although there are philosophical questions about the coherence of such a radical emergentism, exactly such a doctrine was developed in some detail by the likes of Morgan and Broad (see above). So this is a serious defect in Nagel's argument.

Nonetheless, the epistemological form of emergentism is highly congenial to common interpretations of complexity in modern science and is usually what is meant in modern discussions of emergence. Thus the anti-emergence argument can retain some force within that context, if now in an empirical form.

The empirically based forms of the genetic argument have been traditionally more popular. Wundt himself makes an "inference to the best explanation" in defense of panpsychism. He states that panpsychism is "a theory, it is true; but it is the only theory which can explain the phenomena of movement displayed by these primitive creatures" (1892/1894, p. 443). Wundt found it literally incredible that the apparent purposiveness and appropriateness of the behavior of even simply micro-organisms -- which he thought lent themselves naturally to mentalistic explanation -- could spring, suddenly and arbitrarily, into existence through the mere conglomeration, via elementary physical forces, of material particles into complex systems.[9]

But by far the most popular empirical ground for the genetic argument stems from Darwinism, whose ascension in the mid-nineteenth century transformed debate about life and mind. This form of the genetic argument turns on the assumption that evolution is a continuous process that moulds pre-existing properties into more complex forms but which can not produce "entirely novel" properties. An important proponent of this argument was William Clifford. Clifford puts the argument thus: "... we cannot suppose that so enormous a jump from one creature to another should have occurred at any point in the process of evolution as the introduction of a fact entirely different and absolutely separate from the physical fact. It is impossible for anybody to point out the particular place in the line of descent where that event can be supposed to have taken place. The only thing that we can come to, if we accept the doctrine of evolution at all, is that even in the very lowest organism, even in the Amoeba which swims about in our own blood, there is something or other, inconceivably simple to us, which is of the same nature with our own consciousness ..." (1874/1886, p. 266). Another extremely influential figure whose panpsychism rests in part on this idea is William James, who writes that "we ought ... to try every possible mode of conceiving of consciousness so that it may *not* appear equivalent to the irruption into the universe of a new nature non-existent to then" (1890/1950, p. 148).The argument has drawn supporters throughout the twentieth century (see for example Drake (1925), Wright (1953), Waddington (1961) and of course Nagel (1979).

It is difficult to assess this argument, since, for example, the existence of such an obvious example as *wings* seems on the face of it to present a perfectly clear case of the evolutionary development of novel features (as compared, say, to the aviational equipment of the distant single celled ancestors of the birds). It would then be claimed on the other side that wings are nothing but a more complex configuration of matter itself, the possibilities of which configurations are implicit in the pure physics of the DNA based phylogeny of all living things. Wings, and all other materially embodied biological organs, seem clearly to fall under the kind of merely epistemological emergence discussed above. Mind, and especially consciousness, certainly does not seem to be merely a new kind of material organ nor a new kind of behavioral propensity, so there is indeed some cogency in this reply. The panpsychist position would clearly fail if there was a clear and uncontroversial conception of how consciousness emerges, in an ontological rather than epistemological sense, from entirely non-mentalistic physical features, but at present we simply do not possess such a conception, although many controversial suggestions are in play. It is the burden of the emergentist to provide one, or convince us to be content with the brute fact that

mental properties are conditioned by certain physically complex states in a fundamentally inexplicable way. Either task is decidedly non-trivial.

It is also worth noting as an historical point that the empirical version of the above "argument from continuity" was bolstered for some time in the late nineteenth and early twentieth centuries by laboratory research. For example, work of Hans Driesch (1867-1941), famous as one of the last serious defenders of vitalism, a doctrine which had very close connections to panpsychism, and R. Lotze, who was a determined foe of vitalism despite his advocacy of panpsychism (his brand of idealism left the "material world" explicable by mechanical laws) was taken to support panpsychist claims. Both men had taken to dividing up certain creatures, to discover that whole organisms could develop from the parts. Driesch's experiments on sea urchin embryos -- very demanding and cutting edge work at the time -- suggested that every cell of the developing urchin was capable of forming a new embryo. This was taken as evidence that there was some "principle of life" inherent within each cell. In less rigorous experiments, Lotze showed that parts of polyps could grow into complete, new, polyps. A kind of analogical extension suggested that mental properties might be similarly inherent in the basic structures of the world. However, as mysterious and suggestive as such findings might have been in their time, they would seem now to be entirely explicable, albeit only in principle, by modern reductionist DNA based biology; any analogical support they might have offered to panpsychism has thus entirely evaporated. But perhaps other, more direct, analogical arguments might fare better.

4.2 Analogical Arguments

The most straightforward argument from analogy goes like this: if we look closely, with an open mind, we see that even the simplest forms of matter actually exhibit behavior which is akin to that we associate with mentality in animals and human beings. Unfortunately, in general, this seems quite preposterous, and some panpsychists have written some pretty silly things in its defense. For example, Ferdinand Schiller attempted to "explain" catalysis in terms of mentalistic relations: "is not this [that is, catalysis of a reaction between A and B by the catalyst C] strangely suggestive of the idea that A and B did not know each other until they were introduced by C, and then liked each other so well that C was left out in the cold" (as quoted by Edwards (1967) in an acidly humorous paragraph, from Schiller (1907)). Strange? Certainly, but not really very suggestive at all compared to the physical chemists' intricately worked out, mathematical and empirically testable tale of energy reducing reaction pathways. There has always been a strain of mysticism in many panpsychists, who like to imagine they can "sense" that the world is alive and thinking, or find that panpsychism provides a more "satisfying" picture of the world, liberating them from the arid barrenness of materialism and perhaps this leads them to seek analogies somewhat too assiduously (as noted above, Fechner was the most poetical advocate of the mystical appeal of panpsychism and also a fervent advocate of analogical arguments for panpsychism).

A more intriguing hope for an analogical defense of panpsychism springs from the overthrow of determinism in physics occasioned by the birth of quantum mechanics. There have been occasional attempts by some modern panpsychists, starting with Whitehead, to see this indeterminacy as an expression not of blind chance but spontaneous *freedom* in response to a kind of *informational*

inclination rather than mechanical causation. This updated version of the analogy argument has the advantage that the property at issue, freedom, modelled as spontaneity and grounded in indeterminacy, can be found at the most fundamental level of the physical world. As in any analogical argument, the crux of the issue is whether the phenomena cited on the one side are *sufficiently* analogous to the target phenomena to warrant the conclusion that the attributes in question can be extended from the one domain to the other. In this case, we have to ask whether the indeterminacy found at the micro-level genuinely corresponds to what we take freedom to be, and this is doubtful. The indeterminacy of modern physics seems to be a pure randomness quite remote from deliberation, decision and indecision.

But still another analogical argument which draws upon quantum physics is much more promising. The analogy in this case involves the relation between consciousness and information. It is natural to think that among the functions of consciousness is the integration of diverse fields of information and the monitoring of various external and internal states. The consciousness of pain, for example, at least involves the monitoring and processing of information about significant states of the body.[10] In a recent work on consciousness which emphasizes the informational and monitoring functions of consciousness, William Lycan comes surprisingly close to a form of panpsychism when he states that "one little monitor does make for a little bit of consciousness. More monitors and better integration and control make for more and fuller consciousness" (1996, p. 40). This is only intended by Lycan to be part of an account of how consciousness *emerges* which is then forced to allow that consciousness is rather more ubiquitous than untutored intuition might expect. But it follows from this view that *if* information monitoring is a fundamental and pervasive feature of the world at even the most basic levels, then consciousness too should appear at those levels.

It is then highly suggestive that one of the central features of quantum mechanics is the existence of informational but non-causal relations between elements of systems. These relations are non-causal insofar as they are modulated instantaneously over any distance and do not involve the transfer of energy between the parts of the system. But they are informational in the sense that the changes of state of one part of the system seems in some way to be communicated to the other. There is no doubt whatsoever that such quantum systems can exist (they have been created in the laboratory) although the interpretation of them in terms of information exchange is contentious. For example, it is possible to create pairs of photons with correlated polarization states, such that, while neither photon is in a definite state of polarization prior to measurement, they must be discovered to be in opposite polarization states when a measurement takes place, no matter how far apart they are when the measurements occur. Such correlated particles are said to be "entangled". It does not seem unreasonable to regard two such entangled photons as effectively monitoring each other's state of polarization. We can then use a theory of consciousness such as Lycan's to argue that a little monitoring makes for a little bit of consciousness. Furthermore, while entangled states are normally very delicate and susceptible to "decoherence" caused by environmental disturbance, there might be certain systems that can resist decoherence and it has been conjectured that these systems are the physical foundation of more complex states of consciousness (see Hameroff and Penrose 1996; Hameroff, at least, is willing to entertain a panpsychist interpretation of this work). To follow this line of thought even further, the decoherence argument evidently collapses for the universe as a whole, which by definition cannot be disturbed by any outside force, so presumably the total universe is in one immensely complex entangled state. Given a link between consciousness,

monitoring and information exchange, this leads to a view highly reminiscent of Leibniz's monadology, with centres of (perhaps rudimentary) consciousness, or at least mind, at the foundation of the world. Michael Lockwood has developed a highly interesting and well worked out version of this panpsychist view combining quantum mechanical considerations with the intrinsic nature argument, to be considered below, which endorses "a conception of the world as ... a sum of perspectives" (1991, p. 177).

4.3 Intrinsic Nature Arguments

Another possible argument for panpsychism is neither genetic nor analogical but instead depends on the idea that every actual thing, or kind of thing, must have an intrinsic nature. The objects studied by physics, it is claimed, are described in purely dispositional terms. That is, while an electron, for example, is said to possess "spin", all this amounts to is that the electron has certain dispositions to behave in certain ways under certain circumstances. It is arguable that dispositions must be grounded in some intrinsic, non-dispositional attributes, but we have no conception whatsoever of what the intrinsic nature of matter might be. In fact, the only intrinsic nature with which we are familiar is consciousness itself. The qualities of conscious experience (to take simply sensory experience: the smell of a rose, the taste of a strawberry, etc.) seem not to be reducible to relations amongst non-experiential states nor entirely specifiable without remainder in terms of their causal powers to produce behavior (and other mental states). They seem instead to possess (or be) intrinsic and irreducible characteristics. If this is the only idea of intrinsic nature we possess, and matter must be assigned some intrinsic nature, it seems that matter must be granted a mentalistic intrinsic nature. The core idea of this argument can be traced back to Leibniz who felt forced to ascribe mentalistic attributes to his monads as the only possible feature which could make intelligible the active forces that seemed to be required in an adequate physics, and which finally laid to rest the dream of a purely mechanical world view. In his discussion of this difficulty, Whitehead describes all "modern cosmologies" as having to admit a "mysterious reality in the background, intrinsically unknowable" (1933/1967, p. 133) and notes that Leibniz "explained what it must be like to be an atom" (1933/1967, p. 132). See Sprigge (1983) for a defense of this argument within an extended discussion of the virtues of panpsychism (for another brief summary of the argument see Sprigge 1999). Another, less idealist, version of the argument is developed in Lockwood (1991), based upon ideas taken from Russell's later philosophy, married to an interpretation of quantum physics. Although far from demonstrative this is, in the words of Thomas Sprigge (1999), "a hypothesis worth exploring as the only alternative to saying that matter is unknowable in its inner essence, and as likely also to cast light on the mind-body or mind-brain relationship."

Still, one obvious reply to this argument is to bite the bullet of unknowability and accept that the intrinsic nature of matter is either unknown or even essentially unknowable. Belief in such irremediable ignorance would seem neither to entail panpsychism nor to be incoherent, and many might prefer it to panpsychism.

However, recently several philosophers have made remarks somewhat reminiscent of this argument. For example, Galen Strawson has argued for a revised conception of materialism and remarks that "the experiential considered specifically as such -- the portion of reality we have to do with when we consider experiences specifically and solely in respect of the experiential character they have for those who have

them as they have them- that "just is" physical" (1997/1999, p. 7) . Strawson hints that only a "revolutionary development" in physics would allow consciousness to be "discerned and described" by that science. The idea that a revolutionary change in physics may be necessitated by the problem of consciousness is endorsed, suggested or at least hinted at by several distinguished thinkers, including Roger Penrose (1989), John Searle (1991, pp. 123-4), Thomas Nagel (1979, 1986, 1999) and Noam Chomsky (1999; see the remarks about unification and revision on p. 82 for example). Suggestive as these thoughts may be, it only leaves a gap into which the wedge of panpsychism might be inserted. What reason have we to suppose that the hoped for revolution in our understanding of matter at the most fundamental level will involve ascribing essentially *mentalistic* properties to it? The panpsychist's hope lies in the thought that any modification of our conception of the physical that does not incorporate mind will leave us in an essentially unchanged position, with no explanation of how consciousness emerges from the radically non-mental physical elements of the world. We have seen that this argument has been bruited since at least the time of the Presocratics and it has often led emergentists to reconsider their position when the problem of consciousness is directly considered (it is this worry that probably explains why Morgan, a radical emergentist, retreated into a Spinozistic parallelism of mind and matter; see Morgan 1923, p. 32).

This leads to the final consideration in favor of panpsychism to be considered here, which is a sort of methodological argument. Panpsychism enjoys a metaphysical advantage in that it avoids the difficulties of emergentism, which are greater than is generally thought. Not only is there a problem simply in accounting for the emergence of something so distinctive as consciousness from mere matter, it is surprisingly difficult to articulate a form of emergentism that does not threaten to make the emergent features causally impotent or epiphenomenal. This is not the place to discuss the difficulties of all the varieties of emergentism, but they seem serious.

5. Arguments Against Panpsychism

This article would be incomplete without a consideration of some of the objections against panpsychism, but it will also serve to sharpen our understanding of the doctrine to consider possible replies available to the panpsychist.

Perhaps the initially most obvious problem with panpsychism is simply the apparent lack of evidence that the fundamental entities of the physical world possess any mentalistic characteristics. Protons, electrons, photons (to say nothing of rocks, planets, bridges etc.) exhibit nothing justifying the ascription of psychological attributes and thus Occam's razor, if nothing else, encourages withholding any such ascriptions. Furthermore, it is argued, since we now have scientific explanations (or modes of explanation at least) which have no need to ascribe mental properties very widely (it is tempting to interject: not even to *people*!) panpsychism can be seen as merely a vestige of primitive pre-scientific beliefs. At one time, perhaps, panpsychism or animism may have been the conclusions of successful inferences to the best explanation, but that time has long passed.

As we examine ever smaller, more basic units of the physical world, it seems harder and harder even to

imagine that such things have *any* properties that go beyond those ascribed to them by the physical theories which are, after all, the only reason we have to believe in them. In any case, there seems no reason to assign any intrinsic nature to the theoretically postulated entities of physics that goes beyond providing for the causal powers they are presumed to possess according to the theories which posit them. Even granting the need to assign *some* intrinsic nature to matter, it remains far from clear that *mentality* is the intrinsic character required for possession of these causal powers. Some such argument likely accounts for the general sense of implausibility with which many people greet panpsychism nowadays. For example, perhaps a somewhat extreme one, John Searle describes panpsychism as an "absurd view" (Colin McGinn uses the word "ludicrous") and argues that thermostats do not have "enough structure even to be a remote candidate for consciousness" (1997, p. 48).

Another possible, and closely related, diagnosis for the sense of implausibility which panpsychism engenders in many may stem from a certain methodological ideal. The job of philosophers, it may well be thought, is to show how the mind, and especially consciousness, is to be integrated into the scientific world view, or, to use the current term, *naturalized*. It is against the implicit rules of this game to demand that science be changed to accommodate consciousness -- the point is to take science as it is and show that consciousness can be fitted into *that* kind of conceptual structure. This assumes of course that science is, as it stands, or near enough, already true and complete. Thus it is curious to find Searle both advocating that consciousness is a "biological property" whose conditions of emergence are no stranger than those of the liquidity of water, and also hinting that a revolution in our understanding of the physical world will be needed to accommodate consciousness.

Such remarks as Searle's betray emergentist presuppositions as well as assumptions about the nature of consciousness. After all, on the view of Lycan canvassed above it would be difficult to withhold attributing a "little bit" of consciousness to thermostats. In any case, this "no evidence" argument can be weakened by noting that we should not necessarily expect to see signs of complex mentality at the simplest level or perhaps any sign at all. After all, the effects of gravitation are invisible at the level of extremely small sizes and masses but this does not mean that gravitation is insignificant in the universe, nor that it is not a ubiquitous and fundamental feature of the world, of which every existing thing partakes.

A problem very closely related to this difficulty of lack of evidence is this: even if there was a need to revolutionize fundamental physics in order to give an account of consciousness, why would the new features of the transformed physics be *mental* features? One should not ascribe anything more to these new features than what is necessary for them to solve whatever problem in *physics* that prompted their postulation.

Leaving aside how the argument from intrinsic nature impinges on this point, what is crucial here is just how these hypothetical revolutionary features would operate. If they involved basic operations on *informational* states and, for example, the cross monitoring of and by fundamental physical entities (as discussed above) then there might well be some reason to connect them with mentality. It seems that physics *already* has posited something like these informational operations and with them something at least somewhat analogous to aspects of the psychological domain.

This reply, so far as it goes, can also serve to deflect another objection, which is that the mental attributes assigned to the fundamental physical entities by the panpsychist must lack all causal efficacy, that is be entirely epiphenomenal, since the physical world, as described by physics, is *causally closed*. (Something like this argument is advanced by McGinn in his discussion of panpsychism in *The Mysterious Flame* (1999, pp. 95-101), though McGinn tendentiously ignores the distinction frequently drawn by panpsychist's and discussed above between "mere aggregates" and "unities".) That is, for every physical event there is a purely physical explanation for its occurrence and these explanations make no reference to mental properties. This argument suffers from an intentional fallacy. It is possible that some of the properties referred to in physical description of an event and its causes are identical to mental properties. The dispositional aspect of the properties of remote connectedness via informational states that we have been discussing are a part of basic physics but the panpsychist may urge that they also represent the primitive consciousness of the basic entities involved in these interactions. Physics has *described* them in the physical terms appropriate for physical theory, that is, purely in terms of their dispositions to interact with other physical entities in certain ways; this does not preclude their *being* mental properties. Of course, we need some independent argument that these properties ought to be regarded as *mental*, but that is provided, to the extent it can be, by the informational and mutual monitoring aspects of them.

There is another form of the argument from the causal closure of the physical world. One might expect that a fundamental feature as significant as consciousness appears to be should take some part in the world's causal commerce. But if it does play such a role, then we should expect it to turn up in our investigation of the physical world; we should expect, that is, to see *physically* indistinguishable systems at least occasionally diverge in their behavior because of the lurking causal powers of their mental dimension. The argument proceeds with the claim that it is very doubtful that there is any such evidence and, if it were supposed to exist, our physical picture of the world would then be radically *causally* incomplete in contradiction with the world's presumed causal closure at the physical level. The reply in the text serves against this objection as well. But it is also worth noting that, as a matter of fact, physically indistinguishable systems do behave differently from each other; no one knows if some "hidden variables" can be invoked to account for this indeterminism. Perhaps the hidden feature is in some way related to mentality and consciousness -- such is the core notion of panpsychism. If one regards the problem of free will as especially pressing one may be drawn to this second line of reply against the argument from causal closure (one panpsychist who takes this line is Griffin 1998).

We noted above that a common distinction within the field of psychological attributes is that between conscious and unconscious mental states, and several panpsychists have appealed to this distinction in setting forth their doctrines. But there is a danger here that threatens to undercut one of the prime virtues of panpsychism which is the avoidance of emergence. For if the mental attributes which the panpsychist ascribes to the fundamental or simplest entities in the world are all unconscious mental properties, then the question of how *conscious* mental states arise will be inescapable. And this in turn means that we now need a theory of the emergence of consciousness from the merely unconscious mental states licensed by this cautious panpsychism.[11] It is best to cut this line of objection off at the start. The panpsychist needs to bite the bullet here and *postulate* that it is indeed states of consciousness, although presumably with a very impoverished degree and kind of content, which are to be assigned to the most simple elements of

nature.

However, the postulate of primitive consciousness still leaves open a line of objection, call it the "combination problem," which was first raised by William James, who in the following passage argues that panpsychism will still face its own problem of emergence:

> Take a sentence of a dozen words, and take twelve men and tell to each one word. Then stand the men in a row or jam them in a bunch, and let each think of his word as intently as he will; nowhere will there be a consciousness of the whole sentence ... Where the elemental units are supposed to be feelings, the case is in no wise altered. Take a hundred of them, shuffle them and pack them as close together as you can (whatever that might mean); still each remains the same feeling it always was, shut in its own skin, windowless, ignorant of what the other feelings are and mean. There would be a hundred-and-first feeling there, if, when a group or series of such feeling were set up, a consciousness *belonging to the group as such* should emerge. And this 101st feeling would be a totally new fact; the 100 original feelings might, by a curious physical law, be a signal for its *creation*, when they came together; but they would have no substantial identity with it, nor it with them, and one could never deduce the one from the others, or (in any intelligible sense) say that they *evolved* it (1890/1950, p. 160, original emphasis).

This is a powerful objection since if panpsychism must allow for the emergence of states of consciousness then what prevents an emergence doctrine which avoids the implausible and indiscriminate broadcasting of mental characteristics throughout the world?

Note first that a form of panpsychism such as Leibniz's entirely escapes this objection. For Leibniz, minds are not formed out of combinations of parts (whether sub-minds or non-mental entities). Each mind is complete in itself, and in fact totally causally isolated from all other minds; there is no way that the combination problem could arise. However, the cost to Leibniz is the downgrading of the physical world to a kind of "consensual illusion"; matter, space and time are essentially constructs of mental phenomena.

If we wish to retain a robust conception of matter, which is extended but not mutilated by panpsychism, there seems little doubt that we will require a theory of emergence. But it does not follow, at least not directly, that a *non-mentalistic* emergentism is therefore to be favored. That depends upon the nature of the emergence in question. Whitehead, for example, embraced the need for a kind of emergence with no diminishment in his support for panpsychism. As Hartshorne explains, "it is the destiny of the many to enter into a novel unity, an additional reality" which means that Whitehead makes the "admission not merely of emergence, but of emergent or creative synthesis as the very principle of process and reality" (1972, p. 162).

It is clear from the way that James develops his version of the combination problem that he is presupposing a metaphysics of part-whole reductionism such that the properties of the whole are no more

than the sum or combined effect of the properties of the parts, in which the parts entirely retain their identities. For example, he says "... in the parallelogram of forces, the "forces" themselves do not combine into the diagonal resultant; a *body* is needed on which they may impinge, to exhibit their resultant effect" (1890/1950, p. 159). Such a view undoubtedly has a certain attractiveness; it seems no more than a reasonable generalization of the mereological reductionism of which the world provides so much evidence.

But we know that this view is inadequate. Quantum mechanics has made it abundantly clear that systems are not simply the sum of their parts in James's sense but can exhibit properties that go beyond those of the parts and which cannot be detected by examining the parts in isolation. It is impossible to tell if an electron, for example, possesses an entangled partner positron by looking only at the electron and the positron (they individually look identical to non-entangled particles). Yet the system of entangled particles exhibits properties quite distinct from the properties of pairs of non-entangled particles. Thus there *is* a mode of combination which goes far beyond what James allows and which we know is actually at work in the world. This mode of combination also seems to have some intimate connection with information and some sort of non-causal information exchange which, as noted above, has some affinity with psychological notions. (A more detailed examination of this argument can be found in Seager 1999, ch. 9.)

Nevertheless, it obviously remains far from clear that quantum mechanics necessarily leads to panpsychism and one might wish to deploy the powerful theory of emergence which quantum mechanics provides in the service of a more traditional emergentism which sees mind developing from non-mental aspects of nature (such an approach is taken by Silberstein and McGeever 1999). Assessing such a strategy would require consideration of the plausibility of the claim that mind and consciousness can be explicated solely in terms of the physical properties and entities postulated by quantum mechanics, a difficult task beyond the scope of this article, but about which one might harbor some doubts. The point here is simply that the combination problem can be addressed from within a panpsychist framework.

The existence of possible replies to a set of objections does not, in itself, provide positive grounds for endorsing a theory. At present, the predominance of the scientific view of the world, and a general disinclination towards dualistic as well as idealistic metaphysics, brings with it the triumph of emergentism, and the key issue becomes that of assessing the prospects of theories of emergent mentality. All modern physicalistic theories of mind implicitly rest upon a theory of emergence (which is seldom articulated in any detail), but, thus far, none of these has dealt with consciousness in a fully satisfactory way (that is, the problem of the emergence of consciousness has not gone the way of the problem of the emergence of chemistry). Unless and until we have such a satisfactory account, panpsychism remains an open possibility.

Panpsychism is an abstract metaphysical doctrine which as such has no direct bearing on any scientific work; there is no empirical test that could decisively confirm or refute panpsychism. One might complain about this remoteness, as Thomas Nagel does with the remark that panpsychism has "the faintly sickening odor of something put together in the metaphysical laboratory" (1986, p. 49). Nonetheless, metaphysical views form an indispensable background to all science. They integrate our world views and

allow us to situate our scientific endeavors within a larger vista and can suggest fruitful new lines of empirical enquiry (as the example of Fechner's psycho-physics illustrates). In particular, panpsychism accords with an approach that rejects physicalist reductionism at the same time as enjoining the search for neural correlates of consciousness, and it sees, or wants to see, a fundamental unity in the world which emergentism denies. Thus it is not a doctrine at odds with current empirical research.

It has always been and remains impossible to resist metaphysical speculation about the fundamental nature of the world. As long has there been science, science has informed this speculation and in return metaphysics has both helped to tell us what the point of science is and paved the way for new science. Panpsychism remains an active player in this endless speculative interchange.

Notes to Panpsychism

Notes

1. A possible variant is, then, a doctrine which asserts that only *some* of the basic physical constituents of the world possess mental attributes (for example, as it might be, only electrons). Since there seems to be nothing upon which to base excluding certain of the fundamental physical entities from the realm of the mind, and since the panpsychist would regard the position that the physically fundamental entities should be conceived of as potentially mindless as wrongheaded, such a position has never been developed.

2. The appropriateness of the analogy is suspect since energy, although certainly ubiquitous, may not be as fundamental as the panpsychist would wish. The energy of systems is usually reducible, as in the common Hamiltonian description of a system, to velocities, masses and positions (within fields that yield potential energy).

3. Piaget's conclusions may be overstated although animistic tendencies in children are obviously present (for views contrary to Piaget's see Carey 1985, Wellman 1992). It is impossible to resist pointing out that the apparent decline in children's willingness to make widespread mentalistic attributions from 1929 to 1992 may reflect the increasing cultural ascendancy of scientific and materialistic modes of thought over that some time span.

4. Another Presocratic philosopher who has been said to espouse panpsychism for reasons similar in form to those of Thales (that is, via analogy and indeed an analogy with motion production) is Anaximenes (whose dates within the sixth century BC are uncertain), who in some way identified "air" (or "breath") with soul or mind, thus making mind ubiquitous.

5. Empedocles is sometimes regarded as a panpsychist because of the universal role of love and strife (see Edwards 1967 for example) but there seems little of the mental in Empedocles's conceptions, which are rather more like forces of aggregation and dis-aggregation respectively (see Barnes 1982, pp. 308 ff.).

6. It is important to note that although we, overall rightly, regard Newton as one of the founders of the materialist world view he was reluctantly forced to imbue matter with a mysterious power that transcended the pure mechanics of Descartes (hence my scare quotes above). The postulation of a "force" of gravity added an intrinsic power to matter that many, including Newton himself, regarded as inconsistent with a scientific understanding of the world. Some philosophers have seen the notion of force as a transmuted form of the concept of *spirit*, and thus as a limited and covert importation of mentalistic features into matter.

7. The notion that biological species should be thought of as individuals rather than collections of individuals has received some attention in contemporary philosophy of biology (see Hull 1976, DeSousa 1989). It is, of course, another matter whether species, even if they are granted status as individuals, ought to be granted minds but it presumably cannot be ruled out *a priori*.

8. Interestingly, Jaegwon Kim (1999) has recently endorsed the basic cogency of Nagel's argument, though in a back-handed way (Kim, so to speak, favors *modus tollens* over *modus ponens*). Rather than accept any form of panpsychism -- indeed he does not consider the option at all -- Kim prefers to defend physicalism by returning us to the days of reductive materialism; he sees no other way to avoid the charge that mental properties are epiphenomenal. Panpsychism appears to avoid both epiphenomenalism and reductionism, though at the cost of rejecting traditional forms of physicalism.

9. The mental lives of protozoa was apparently a lively topic at the time. Alfred Binet, the pioneer in intelligence testing, wrote the intriguingly entitled *Études de psychologie expérimentale: le fétichisme dans l'amour, la vie psychique des micro-organismes, l'intensité des images mentales, etc.* in 1891 (an English translation -- *The Psychic Life of Microorganisms* -- appeared in 1889).

10. Recent defenders of the so-called representational thedefense of consciousness (see for example Dretske 1995 or Tye 1995) contend that the informational aspect of consciousness exhausts its nature. We need not go so far here; it is enough that consciousness clearly does possess such an aspect.

11. Someone with preexisting emergentist leanings will tend to see this as trivialising panpsychism or rendering it empty. As McGinn says: "the weak version [of panpsychism] says that matter has some properties or other, to be labeled "proto-mental", that account for the emergence of consciousness from brains. But of course *that* is true" (1999, p. 99).

Pantheism

Pantheism is a metaphysical and religious position. Broadly defined it is the view that (1) "God is everything and everything is God ... the world is either identical with God or in some way a self-expression of his nature" (Owen 1971: 74). Similarly, it is the view that (2) everything that exists constitutes a "unity" and this all-inclusive unity is in some sense divine (MacIntyre 1967: 34). A slightly more specific definition is given by Owen (1971: 65) who says (3) "‘Pantheism’ ... signifies the belief that every existing entity is, only one Being; and that all other forms of reality are either modes (or appearances) of it or identical with it." Even with these definitions there is dispute as to just how pantheism is to be understood and who is and is not a pantheist. Aside from Spinoza, other possible pantheists include some of the Presocratics; Plato; Lao Tzu; Plotinus; Schelling; Hegel; Bruno, Eriugena and Tillich. Possible pantheists among literary figures include Emerson; Walt Whitman, D.H. Lawrence, and Robinson Jeffers. Beethoven (Crabbe 1982) and Martha Graham (Kisselgoff 1987) have also been thought to be pantheistic in some of their work-if not pantheists.

The book recognized as containing the most complete attempt at explaining and defending pantheism from a philosophical perspective is Spinoza's *Ethics*, finished in 1675 two years before his death. In 1720 John Toland wrote the *Pantheisticon: or The Form of Celebrating the Socratic-Society* in Latin. He (possibly) coined the term "pantheist" and used it as a synonym for "Spinozist." However, aside from some interesting pantheistic sounding slogans (like "Every Thing is to All, as All is to Every Thing"), and despite promising "A short Dissertation upon a Two-fold philosophy of the Pantheists" Toland's work has little to do with pantheism.

Pantheism and Theism

Where pantheism is considered as an *alternative* to theism it involves a denial of at least one, and usually both, central theistic claims. Theism is the belief in a "personal" God which in some sense is separate from (transcends) the world. Pantheists usually deny the existence of a personal God. They deny the existence of a "minded" Being that possesses the characteristic properties of a "person," such as having intentional states, and the associated capacities like the ability to make decisions. Taken as an alternative to, and denial of, theism and atheism, pantheists deny that what they mean by God (i.e. an all-inclusive divine Unity) is completely transcendent. They deny that God is "totally other" than the world or ontologically distinct from it. The dichotomy between transcendence and immanence has been a principal source of philosophical and religious concern in Western and non-Western traditions; and all major traditions have at times turned to pantheism as a way of resolving difficulties associated with the theistic notion of a transcendent deity or reality.

Not all of the problems generated by the theistic notion of God are also problems for pantheism. But given a suitable reformulation, some of them will be. And, as expected, pantheism will also generate some difficulties peculiar to itself. Thus, although evil and creation do not present identical problems for pantheism and the theism, and may even be inherent to theism; it *may* also be possible to reformulate them in a way that makes them applicable to pantheism. There may be pantheistic counterparts to the problem of evil and other classical theistic problems, and perhaps they can be resolved by pantheism.

There are probably more (grass-root) pantheists than Protestants, or theists in general, and pantheism continues to be the traditional religious alternative to theism for those who reject the classical theistic notion of God. Not only is pantheism not antithetical to religion, but certain religions are better understood as pantheistic rather than theistic when their doctrines are examined. Philosophical Taoism is the most pantheistic, but Advaita Vedanta, certain forms of Buddhism and some mystical strands in monotheistic traditions are also pantheistic. But even apart from any religious tradition many people profess pantheistic beliefs-though somewhat obscurely. Pantheism remains a much neglected topic of inquiry. Given their prevalence, non-theistic notions of deity have not received the kind of careful philosophical attention they deserve. Certainly the central claims of pantheism are *prima facie* no more "fantastic" than the central claims of theism-and probably a great deal less so.

Is Pantheism Atheistic?

Like "atheism" the term "pantheism" was used in the eighteenth century as a term of "theological abuse," and it often still is (Tapper 1987). A.H. Armstrong says the term "pantheistic" is a "large, vague term of theological abuse," (Armstrong 1976: 187). With some exceptions, pantheism is non-theistic, but it is not atheistic. It is a form of non-theistic monotheism, or even non-personal theism. It is the belief in one God, a God identical to the all-inclusive unity, but pantheists (generally) do not believe God is a person or anything like a person. The fact that pantheism *clearly* is not atheistic, and is an explicit denial of atheism, is disputed by its critics. The primary reason for equating pantheism with atheism is the assumption that belief in any kind of "God" must be belief in a personalistic God, because God must be a person.

In his non-pantheistic phase, Coleridge claimed that "every thing God, and no God, are identical positions" (McFarland 1969: 228). Owen (1971: 69-70) says, "if ‘God’ (theos) is identical with the Universe (to pan) it is merely another name for the Universe. It is therefore bereft of any distinctive meaning; so that pantheism is equivalent to atheism." Similarly, Schopenhauer (1951: 40) said that "to call the world ‘God’ is not to explain it; it is only to enrich our language with a superfluous synonym for the word ‘world’." The charge that pantheism is atheistic is as old as pantheism itself. Christopher Rowe (1980: 54-5) says, "When Cicero's Velleius describes Speusippus' pantheism as an attempt to ‘root out the notion of gods from our minds’, he is echoing a charge which was commonly made against the pantheism of the earlier Greek natural philosophers ... like Anaximander or Heraclitus. These tended to be identified as atheists in the popular mind; and indeed Plato himself implies a similar view ... the opponents who classify them as atheists are in reality attacking them for undermining traditional beliefs about the gods-or, to borrow a phrase from the indictment against Socrates, ‘for not believing in the gods the city believes in’."

At most, what Schopenhauer, Coleridge, Owen etc. can show, and probably all they intend, is that the pantheistic Unity can be explained in terms that would either eliminate the notion of deity from pantheism altogether, or that it is incoherent. They want to show that believing in a pantheistic God is a convoluted and confused way of believing in something that can adequately be described apart from any notion of deity-and in this they are mistaken.

Unity

Different versions of pantheism offer different accounts of the meaning of "unity," and "divinity." There is no one meaning in all forms of pantheism, and within some forms several types are found. Often, the meaning of unity present is vague and indeterminate. Because of this, the central problem of pantheism, unlike theism, is to determine just what pantheism means. For example, philosophical Taoism is one of the best articulated and thoroughly pantheistic positions there is. The *Tao* is the central unifying feature. What kind of unity is (or should be) claimed by pantheists and which, if any, is plausible? After dealing with these fundamental questions, the philosophical and religious consequences of analyzing unity in some particular way can be examined. There may be acceptable alternative criteria of Unity. But even if

there are alternatively acceptable criteria, some may be more acceptable to the pantheist than others-given criteria of adequacy in addition to those necessary. Among those that are acceptable, they need not be equally acceptable. However, just as there are alternative theisms, one would expect that there are alternative pantheisms. Pantheism need not be, any more than theism needs to be, a univocal view.

Misunderstandings

Schopenhauer criticized pantheism's identification of "the world" with "God," on the basis of what he took to be the meanings of both for the pantheist. He said calling the world "God," or God "the world," is "superfluous," and redundant. He also ridiculed the idea that the world could be called God given our general notions of what God and the world are like. Schopenhauer's criticism fails because he equivocates on the terms central to his argument. The meanings of both Unity and divinity involved in the pantheistic claim that there exists an all-inclusive divine Unity are different than the senses Schopenhauer attributes to the world and God in his criticism. The pantheist does not mean what Schopenhauer means by God, and the "all-inclusive unity" in pantheism is not another word for the "world" as he uses it (i.e. everything). The interpretation of "world" Schopenhauer attributes to pantheists is not what they mean when they describe it as a Unity.

For the pantheist, however Unity is interpreted, the world is not simply an all-inclusive Unity in the sense that the world, understood to be everything, is the "unity" composed of everything. This would be to interpret it as asserting that everything that exists simply is everything that exists; or to put it another way, everything is (of course) all-inclusively everything. This is true but vacuous, and it trivialises pantheism at the outset.

Attributing Unity simply on the basis of all-inclusiveness is irrelevant to pantheism. Formal unity can always be attributed to the world on this basis alone. To understand the world as "everything" is to attribute a sense of unity to the world, but there is no reason to suppose this sense of all-inclusiveness is the pantheistically relevant Unity. Similarly, unity as mere numerical, class or categorical unity is irrelevant, since just about anything (and everything) can be "one" or a "unity" in these senses. Suppose "formal unity" to be "the sense in which things are only in virtue of the fact that they are members of one and the same class ... the same universal" (Demos 1945-6: 534-545). Then clearly formal unity is not pantheistic Unity. Furthermore, formal unity neither entails or is entailed by types of unity (e.g. substantial unity) sometimes taken to be Unity. Hegel's *Geist*, Lao Tzu's *Tao*, Plotinus' "One," and arguably Spinoza's "substance," are independent of this kind of formal unity.

Unity is explained in various ways that are often interrelated. These connections range from mutual entailment, to different types of causal and contingent relations. Roughly, Unity is interpreted 1) ontologically; 2) naturalistically-in terms of ordering principle(s), force(s) or plans; 3) substantively-where this is distinguished from "ontologically"; and 4) genealogically-in terms of origin. Christopher Rowe (1980: 57) calls 4 a "genealogical model of explanation" of unity. "Thales, Anaximander, and Anaximenes, the Milesian monists appear to have claimed that what unifies the world is that it sprang from a single undifferentiated substance.

Unity may have to be explained partly in terms of divinity. The all-inclusive whole may be a Unity because it is divine-either in itself (Spinoza's substance), or because of a divine power informing the whole-as with the Presocratics. The Presocratics give an account of why they think the unifying principle is divine. It is immortal and indestructible. But this does not satisfactorily explain the relation between Unity and divinity, or why divinity might be seen as a basis of Unity. Similarly, though less naturally, the question arises as to whether the all-inclusive whole is divine because it is a Unity. Can Unity be a basis for attributing divinity to the whole? If divinity is the basis for Unity, as it may be for the Presocratics; or alternatively if Unity is the basis for divinity; then there is something of a redundancy in the definition of pantheism as the belief that everything that exists constitutes a divine Unity. A simpler non-redundant definition would be that pantheism holds that "everything is divine".

Divinity

"Divine" is defined as pertaining to God ("of, from, or like a god"), but also as "sacred" or "holy." Either definition suits the present purpose, since determining why pantheists regard the Unity as divine, or god, is equivalent to determining why they regard the Unity to be sacred or holy. The idea of "divinity" in pantheism is similar in some respects to its theistic meaning.

Why do pantheists ascribe divinity to the Unity? The reason is similar to why theists describe God as holy. They experience it as such. In Otto's (1950) experiential account, what is divine is what evokes the numinous experience. This can be a theistic god, but it can also be a pantheistic Unity. And, when looked at from socio-scientific perspectives in terms of how the concept of divinity functions intellectually and affectively (e.g., its ethical, soteriological and explanatory roles), its application in theism and pantheism is much the same.

There is no reason to suppose the idea of "divinity" relevant to pantheism should be modelled after a specific tradition's concept of divinity-like Christianity. At best, this tradition-dependent concept would be relevant to Christian/pantheist and other theist/pantheist hybrids (e.g. panentheism). It is too specific for any general analysis of pantheism, and it refers to the theistic variants of pantheism which are most inconsequential for pantheistic practice.

Whatever criteria are decided upon as necessary for attributing divinity to something, one cannot decide *a priori* that the possession of divinity requires personhood without ruling out the possibility of the most typical types of pantheism (i.e. non-personal types). After all, theism is what pantheism is most of all trying to distance itself from. I am not sure the reverse is true-but theism does ordinarily strongly oppose itself to pantheism. In any case, Spinoza's God and Lao Tzu's *Tao*, for example, are distinctly non-personal, as are the governing principles of the Presocratics. It seems unwarranted, therefore, to suppose that a necessary condition of something's being divine is that it be personal on the grounds that "Of all the modes of creaturely existence, personality is the highest and so the fittest to serve as an analogy of divine being" (Macquarrie 1984: 42). At least to do so begs the question against Spinoza, some of the Presocratics, Lao Tzu, probably Plotinus, as well as against experiential and socio-scientific accounts of

divinity.

Monism

Following a long and still current tradition H.P. Owen (1971: 65) claimed that "Pantheists are 'monists'...they believe that there is only one Being, and that all other forms of reality are either modes (or appearances) of it or identical with it." Although, like Spinoza, some pantheists may also be monists, and monism may even be essential to some versions of pantheism (like Spinoza's), pantheist's are not monists. Like most people they are pluralists. They believe, quite plausibly, that there are many things and kinds of things and many different kinds of value. Even in Spinoza's case, explaining his pantheism in terms of his substance monism glosses the far more significant, pantheistically speaking, evaluative implications he sees as entailed by that monism for his pantheistic metaphysic and his concept of Unity. The *Ethics* is not about monism, but about what it entails. Why Spinoza sees things as a Unity cannot be explained wholly or even primarily in terms of his monism.

Whether or not substance monism is ontologically necessary for Unity, an explanation of its relevance requires something extra-ontological to be cited. The same is true of any factual ground for Unity. Delineating metaphysical or modal properties of a substance, or anything else, does not make their relevance to Unity obvious. So what if everything is made from one self-subsistent immutable substance? So what if everything is really a single organism when considered macrocosmically? Why would this be pantheistically, rather than merely metaphysically significant? What is the evaluative or religious significance of natural features of the totality that pantheism claims is central to Unity? Because value must be partly constitutive of Unity, it must be explained in partly evaluative terms. This is a necessary condition for an adequate criterion of Unity. Without it one is left only with this or that fact as a basis for positing Unity, but no adequate account of the relevance of the basis, and so no account of Unity itself.

There may be ways of conceiving of the monistic "One" such that it is taken both as a unity and as "divine"-yet still not as a pantheistic Unity. The monistic unity (the "One") may not be regarded as a "Unity" (i.e. unity in some relevant pantheistic sense). Not just any monistic unity (e.g. mere substance monism) suffices for pantheism, whether or not it is also regarded as divine. Thus, although Hegel conceived of Reality as unified and rational in terms of the Absolute (Geist), and in a manner that I take it would qualify Geist as divine, he denies he was a pantheist. Similarly, Sankara's Brahman is ontologically all-inclusive and is part of a metaphysical account of the nature of Reality that is religiously significant (i.e. "Reality" is divine in some sense). However, it may be denied that advaita Vedanta, although monistic, is pantheistic. "Unity" is seen as absent from, or even antithetical to, essential aspects of advaita Vedanta such as its monism.

Monists, like pantheists, believe that Reality, or an aspect of it, is "One" or unified. Of course they also deny it is "One" or a "unity" in most other senses. Whatever similarities there are in this regard, there is insufficient reason for attributing pantheism to monists, because the oneness of Reality is neither a necessary nor sufficient condition of pantheism. It is at most a necessary condition if monistic "oneness" is construed in a unitive sense that is constitutive of some particular pantheistic account of the divine

Unity. An alleged entailment between pantheism and monism is even less likely since pantheists, like everyone else, are generally pluralistic. Any appearance to the contrary has been fostered by simply conflating Unity with monism, or by considering the few pantheists who were also monists and taking them as the norm. The connection between Spinoza's monism and his pantheism, does not rest on an identification of the two positions, but is instead the result of the wider metaphysical position constructed in his *Ethics*.

Substance monism need not have any implications concerning God or an Absolute in either a theistic or pantheistic sense. Differences among substance monists may be greater than differences between monists who deny and theists who affirm that God and creation are substantially distinct. For example, a substance monist (e.g. &Sankara-interpreted atheistically) need not identify substance with God, or recognize any God, at all. In this case it is plausible to hold that the difference between such an atheistic monist and a theistic or pantheistic monist is far greater than that between the theistic monist who perhaps holds that creatures and creator are co-substantial (though the theistic monist need not hold this view), and the theistic non-monist who believes that all creatures are substantially distinct from the creator. The latter two have their theism in common, while the former two have their monism in common. The latter two are "closer" in kind than the former, if (and so far as) one assumes that theism is a more significant common denominator than monism.

Transcendence

Like the notions of "Unity" and "Divinity," understanding transcendence and immanence is essential to any account of pantheism. A defining feature of pantheism is allegedly that God is wholly immanent. However, what is actually (or mostly) involved in this claim is that pantheism denies the theistic view that God transcends the world. Pantheism clearly does not claim that God in the theistic sense is immanent in the world since it denies such a God -- transcendent or immanent-exists. According to pantheism it is (of course) the pantheistic "God" (i.e. the all-inclusive divine Unity) that is immanent, not the theistic one. Theists and pantheists do not differ as to whether the theistic God is immanent or transcendent, but whether the theistic God exists. So to differentiate between them on the basis of one's affirming and the other denying immanence is utterly confused.

Many of the difficulties associated with theistic transcendence are not dissipated for the pantheist when relevantly adjusted. For example, theistic transcendence presents *prima facie* difficulties concerning knowledge of and relations with God. The pantheist is part of the Unity, but both the nature of Unity, and its practical implications must be determined. In the *Meditations* of Marcus Aurelius this appears as much a problem for pantheists, if Aurelius is one, as knowing and relating to God is for theists.

In a sense, the Unity in pantheism is wholly immanent, but this is bare ontological immanence that follows from the Unity's all-inclusiveness (i.e. there is nothing else). Yet even this overstates the pantheistic commitment to immanence. Aspects of the Unity or the unifying principle often have a transcendent aspect to them. Unity is "all-inclusive" but with the possible exception of Spinoza, pantheists generally deny complete immanence. Thus, the metaphysical *Tao* informs everything and is part of the all-

inclusive Unity, but it does have a transcendent aspect to it. It does transcend the phenomenal world of "myriad things." The same is true of Hegel's *Geist*, the Plotinian "One," and Presocratic unifying principles as well. So the claim that pantheists deny "God's" transcendence is altogether misleading on several counts unless taken to mean what it usually does mean when asserted by theists-which is that pantheists deny the transcendence of a theistic God.

If pantheism is seen as the quintessential expression of divine immanence, then it is not difficult to see why it might be combined with panpsychism or animism. Like pantheism, both of these express a kind of pervasive immanence-"mind" in the former case and "living soul," "spirit," or "animal life" in the latter. But however consonant or combined with pantheism these may be, they should be distinguished from both from each other and from pantheism. None of these three views entail one another, and the suggestion that pantheism and panpsychism naturally go together is vague apart from specific accounts of the two positions.

What immediately sets panpsychism apart from pantheism is its belief that mental activity, usually of a kind we can only at times be mildly aware of, is all-pervasive. Although such a supposition is not necessarily inconsistent with pantheism, it is not part of pantheism. Pantheism does not imply that the material/immaterial, or organic/inorganic dichotomies must be rejected. It does not reject these distinctions, but implies that Unity ranges over such divisions. There are other major differences between the two positions as well. Pantheism is a much broader theory. It has implications beyond the scope of panpsychism where the latter is seen as an account of the origin of mind and the relation between mind and matter.

Animism, panpsychism, and especially the doctrine of a world-soul as embodied in the macrocosm/microcosm distinction, have at times been equated with pantheism. These positions may be intrinsic to particular versions of pantheism, but pantheism as such is broader than these and distinct from them.

Creation

"Why is there something rather than nothing?" Pantheism rejects the theistic response that God exists necessarily and freely creates the universe from nothing. But does pantheism require an alternative doctrine of creation? What might such a doctrine be? For pantheism, creation remains problematic and even mysterious. However, difficulties associated with the theistic doctrine of creation *ex nihilo* (i.e. God creating the world out of nothing) vanish. If pantheism requires a creation doctrine, some type of emanationism seems most plausible. This is the type usually associated with, and probably most congenial to pantheism (e.g. Taoism, the Stoics, Plotinus) -- although pantheists can also eschew such doctrines.

Assuming pantheism does require a doctrine or view about creation, what can be said positively about it? Pantheism has a range of options unavailable to theism since the theistic doctrine is extrapolated from scripture. A pantheist might be a kind of existentialist with regard to questions like "Why is there

anything at all?" They could believe existence is a brute fact, with no explanation possible. This might be seen as a refusal to deal with the issue of creation-as rejecting the idea that pantheism requires a theory of creation suited to the notion of a divine Unity. But this is not necessarily so. For all its seeming negativity, this is a positive position and not one that simply denies other views. It is a theory of origin or creation that could be acceptable to some pantheists.

One reason any account of origin, including the view of existence as a brute fact, might be rejected as being especially relevant to pantheism, is that the account is not thought to be intrinsically connected to the notion of Unity. Indeed, pantheists might reject the idea that they require an account of creation intrinsic to their idea of Unity. Instead, *any* account that does not conflict with the way in which Unity is conceived of might be accepted.

In distinguishing between creation *ex nihilo* and emanationism as he does, Macquarrie (1984: 34-5) makes it easy to see why emanationism is often closely associated with pantheism. Emanationism is the view that "creation" is not a "making," but in some sense a "flowing forth" from God or its origin, as Macquarrie puts it. And, what "flows forth" "maintains a closer relation to [its] origin. It participates in the origin, and the origin participates in it." He says, "...emanationism does not necessarily lead to pantheism, but it does imply that in some sense God is in the world and the world is in God."

Even though doctrines of creation *ex nihilo* do not necessarily conflict with that central pantheistic claim, they are usually seen as doing do-partly because they are associated with other incompatible theistic elements (e.g. the creator is a person). On the other hand, emanationism appears to provide a doctrine which-if not an explicit ground on which to base pantheism-is at least one that is seen as congenial. As a doctrine of creation, it may even provide a partial basis for pantheism-as it has (arguably) for Plotinus, Eriugena, and even for Spinoza where "God" is the immanent cause of all things. The view that God is the "immanent cause" of things is a kind of creation doctrine for Spinoza and a basis for Unity. So far as Lao Tzu has a doctrine of creation it too is emanationist. "The Tao engenders one, One engenders two, Two engenders three, And three engenders the myriad things" (*Tao Te Ching*, XLII) (Ku-ying 1981: 49). The *Tao* is "the primordial natural force, possessing an infinite supply of power and creativity" (Ku-ying 1981: 6). Not only does the *Tao* create things-it is responsible for, or makes possible, their growth. "It nourishes them and develops them ... provides for them and shelters them"(*Tao Te Ching,* LI).

Emanationism tends to affirm rather than deny a common ontological, substantial, and evaluative base among everything that exists (e.g., whatever it is which creatively emanates, it is "Good"). It is therefore seen as in keeping with the central tenets of pantheism, and where pantheists adhere to a doctrine of creation it tends to be emanationist. Since Unity must partly be explained evaluatively, the fact that emanationism is often linked to the "Good" provides further reason for supposing it consonant with pantheism. Thus, although Macquarrie is right in claiming that the emanationist view of creation "does not necessarily lead to pantheism," the implication is that it often does.

Evil

The problem of evil is basically a theistic one that is not directly pertinent to pantheism. It is not, as Owen (1971: 72) claims, "an embarrassment" intellectually speaking, to pantheists, nor can it be. The "problem of evil," as it appears in classical theism, cannot be relevant to pantheism since pantheism rejects all of the aspects of theism that are essential to generating the problem. The "problem of evil" is peculiar to theism. This conflicts with the common view among Spinoza's earliest critics that pantheism, unlike theism, can neither account for evil nor offer any resolution to the problem of evil. The reason for claiming pantheism cannot account for evil usually rests on an unwarranted conflation of pantheism with monism, and on the even more untoward supposition that the pantheist's "God" is "theistic" in important respects.

It is not the case that pantheism need not address the existence of evil and associated moral issues. It offers both its own formulation(s) of a "problem of evil" and its own responses. However, the very idea of evil may be something the pantheist wishes to eschew. "Evil" is essentially a metaphysical rather than a moral concept; or it is moral concept with a particular theistic metaphysical commitment. The pantheist may prefer, as most contemporary ethical theorists do, to talk of what is morally or ethically right and wrong. The term "evil" could be retained and applied to particular (usually extreme) instances of moral wrongness, but it would be understood in a sense that divorces it from its original theological and metaphysical context.

Given the classical argument from evil in either its logical or empirical versions it is surprising that anyone should think evil presents any problem whatsoever for the pantheist; for example, that evil counts against the existence of the pantheistic Unity in a way similar to the way in which it counts against the existence of the theistic God. Evil might be taken to be indicative of a lack of pantheistic Unity, as evidence of some kind of chaos instead. But it cannot count against the existence of a pantheistic Unity in the way it can count against the existence of a theistic God. The argument from evil states that given the following propositions it is either impossible that God exists, or it improbable that God exists. 1) God is omnipotent, omniscient, and perfectly good. 2) God would prevent all preventable evil. 3) The world contains preventable evil. The pantheist rejects the proposition needed to generate the problem to begin with. The pantheist accepts (3) "The world contains preventable evil." The pantheist also accepts that if there was a theistic God, which for the pantheist *ex hypothesi* there is not, then (2) "God would prevent preventable evil." But the pantheist rejects (1) "God is omnipotent, omniscient, and perfectly good." Undeniably there is evil in the world that could be prevented, and supposing there was a theistic God one would assume that he would prevent it. But since there is no such God why suppose that proposition (3) requires some kind of special explanation or is cause for any "unease" on the part of the pantheist? The existence of preventable evil, for all that has been, does not even constitute a *prima facie* reason for rejecting the coherence of a pantheistic notion of Unity, or the probability of the existence of Unity. (3) is not incompatible with anything the pantheist believes to be true. Certainly it is not incompatible with (1) since the pantheist denies the truth of (1), and it is not incompatible with (2) which is only hypothetically true for the pantheist. The pantheist has no need to explain evil, or to explain evil away-at least not in any way resembling theism's need to do so.

Evil may be a problem for the pantheist, but it is not the kind of problem that it is for the theist. It does not even conflict, *prima facie* with the existence of a divine Unity. Pantheism does not claim that its divine Unity is a "perfect being" or being at all (generally), or that it is omniscient etc. Surely it is mistaken to

interpret Spinoza's "God" as "perfect" and "omniscient" etc. in anything like the way these predicates are interpreted theistically as applying to God. It might be supposed that the existence of evil is inconsistent or incongruous with the "divinity" of the Unity. But this would have to argued. In theism it is assumed that what is divine cannot also be (in part) evil. But why assume this is the case with pantheism? Even in Otto's account of the "holy" the holy has a demonic aspect. There seems little reason to suppose that what is divine cannot also, in part, be evil. At any rate, there is little reason for the pantheist to argue that what is divine can also be evil, since they can deny that evil falls within the purview of the divine Unity. To say that everything that exists constitutes a divine Unity (i.e. pantheism's essential claim) need not be interpreted in such a way so that it entails that all parts and every aspect of the Unity is divine or good. There can be a Unity and it can be divine without everything about it always, or even sometimes, being divine.

Ethics

Pantheists, like theists, tend to be "moral realists." They believe it is an objective fact that some kinds of actions are ethically right and others wrong, and what is right and wrong is independent of what any person thinks is right and wrong. With the exception of religious ethics, moral realism has not been a widely accepted philosophical position in recent times. However, the pantheist, like the theist, is not troubled by the fact that her moral realism is based on metaphysical assumptions that some regard as otiose. Furthermore, pantheists, like theists, generally think that moral judgements, and value judgments generally, are not empirically verifiable-at least not in the way one verifies matters of fact generally.

"Natural properties" are properties such as being a certain colour, shape, temperature or height, causing pain, "producing the greatest good for the greatest number" etc. They are properties that one can, in principle, verify that an object or action has or lacks. Some ethical "naturalists" (e.g., some Utilitarians) claim that moral properties are identical with natural properties. For example, a morally right action is sometimes equated with the action which "produces the greatest good for the greatest number." Others claim that moral properties are entailed by natural properties. Pantheists, however, generally believe that moral properties are both distinct from natural properties and are not entailed by them. Thus, they are usually "nonnaturalists.

Despite their nonnaturalism, pantheists, like theists, reject G.E. Moore's contention that these properties (i.e. goodness and badness) are ultimate and irreducible. For the theist the fact that "X is wrong" will be explained, and partially analysed, in terms of (even if not reducible to) nonnatural facts about God's will and nature. And, for the pantheist the fact that "X is wrong" will be explained, and partially analysed, in terms of (even if not reducible to) nonnatural facts about the divine Unity. Nonnaturalism is the position most congenial to pantheism, but a pantheist could make a case for being an ethical naturalist just as one could argue for a naturalistic theistic ethics.

Pantheism leaves the option between ethical naturalism and ethical nonnaturalism open. For the pantheist, though perhaps not for the theist, value-properties and predicates may be empirical or natural, or supervene upon natural properties, even if they are not entailed by such properties. So pantheists may be

ethical naturalists. This may be the case even if assertions containing value predicates are not taken to be empirically verifiable in any straightforward way as they often are for naturalism. Such value-predicates are not "empirical" in a narrow sense in which facts in the physical or even psychological sciences are empirical; but neither are they facts about some transcendent reality. Pantheism may, in a sense, deny the existence of any properties that are not "natural." It depends on how much one is willing to broaden one's notion of "natural." Of course, classifications such as "objectivist" and "nonnaturalist," are only a partial explanation of pantheists' ethical views.

Ecology

It is not accidental that pantheism is often taken to be a view inherently sympathetic to ecological concerns. This makes a decision to deal with ecology alongside pantheistic ethics less artificial than it might be if I were discussing, for example, theism and ethics-or a particular normative theory of ethics. There is a tendency to picture pantheists (i.e. pantheists other than Spinoza), outdoors and in pastoral settings. This has roots in the Stoics' veneration of nature, and in the much later nature mysticism, and perhaps pantheism, of some of the nineteenth century poets such as Wordsworth and Whitman. It has been fostered in the twentieth century by pantheists such as John Muir, Robinson Jeffers, D.H. Lawrence and Gary Snyder who explicitly "identify" with and extol nature, and claim people's close association and identification with "nature" and the "natural" is necessary to well-being. The belief in a divine Unity, and some kind of identification with that Unity, is seen as the basis for an ethical framework (and "way of life") that extends beyond the human to non-human and non-living things. The divine Unity is, after all, "all-inclusive."

A pantheistic ecological ethic will not be anthropocentric. This rules out the notion of man as a "steward of nature," whether his own or God's, who is responsible for nature. It also rules out utilitarian, contractarian, and Kantian approaches as providing an ultimate basis since they are anthropocentric. It does not, however, rule out contractarian etc. principles as useful guides to making and justifying environmental decisions. Applying anthropocentrically conceived principles to environmental issues would suffice in many cases, but not all, to sound reasoning about the environment. (The practical problem environmentally speaking has been that almost no principles have been applied until recently. Selfish economic "forces," i.e. people, have ruled without restraint.) The situation here is no different than with respect to theism. For the theist, ultimate justification of ethics resides in a view about the nature of God. But the theist is not prevented, *qua* theist, from invoking less ultimate ethical principles.

The pantheist's ethic, her environmental ethic and her ethics more generally, will be metaphysically based in terms of the divine Unity. It will be based on the Unifying principle which accounts for an important commonality, and it will be the grounds for extending one's notion of the moral community to other living and non-living things. Everything that is part of the divine Unity (as everything is) is also part of the moral community. Aldo Leopold (1949: 219, 240) says, "The land ethic simply enlarges the boundaries of the community to include soils, waters, plants, and animals, or collectively, the land ... A thing is right when it tends to preserve the integrity, stability, and beauty of the biotic community. It is wrong when it tends otherwise." Looking towards pantheism as a metaphysical justification of, for example, Leopold's

"land ethic" is not unreasonable-or no more unreasonable than pantheism itself is.

An anthropocentric view of morality can at best make the non-human and non-living world an object of moral consideration. But it cannot, according to some, provide a basis for regarding those things as having a "good" of their own or as being non-human members of a moral community. Pantheists (and theists) will generally reject any environmental ethic as unsound if it fails to regard the non-human world as a full-fledged member of the moral community. In their view, to do otherwise is ultimately to rest the prospects of environmental well-being on the good will of the only members of the moral community there are-humans. This is seen like resting the welfare of colonies on the goodwill of the colonisers. In order to enlarge our understanding of the moral community in the appropriate ways a metaphysical basis for an environmental ethic is needed which limits the significance of the anthropocentric view.

Furthermore, it is clear that those, like deep ecologists, who argue that our notion of the moral community must be enlarged to include the "good" of the non-human and non-living, and that it is metaphysically correct to do so, also claim that practical consequences *are* involved. The issue is not merely one of providing a rational basis for an environmental ethic.

It may seem that pantheists can claim that ethics and an approach to ecology should be kept separate from, or that they are separate from, the more general pantheistic view that asserts the existence of a divine Unity. A kind of "separation between church and environment" might be proposed. But I doubt that such a separation is possible. The pantheist, like the theist or atheist takes the nature of reality as determinative of ethical requirements. Since Unity is predicated upon some evaluative consideration (e.g. the divine Unity being constituted on the basis of "goodness"), value is a focal point for the pantheist and a principle concern. This situation in regard to pantheism is not too different than the one for theism. For the theist, ethical requirements and evaluative concerns of all sorts are connected to God's alleged goodness, and overall nature.

Salvation and Immortality

Like the term "evil," "salvation" may be rejected pantheists as being too integral to the theistic world view they reject. It is a term borrowed from theism and one not consonant with pantheism. I use the term "salvation" with this in mind.

Pantheistic ethics are, in some ways, Aristotelian. For pantheism the notion of "the good life" as a regulative ideal-a *telos* or end to be strived for-is an aspect of salvation. This can be explained by examining some similarities between pantheistic ethics and Aristotelianism. The pantheist has what Paul Taylor (1975: 132) calls "an essentialist conception of happiness." Like the Aristotelian; Platonist; and theist-the pantheist's conception of happiness "presupposes that there is such a thing as an essential human nature." They all disagree as to what that essential nature is. The pantheist's conception of human nature, her philosophical anthropology, is generally broader and less specific than the others. When goals are stipulated that man *qua* man should achieve this indicates an essentialist conception of human nature.

Furthermore, in an essentialist conception of happiness (one which presupposes that there is such a thing as an essential human nature), "happiness" is largely a function of how well one fulfils one's essential nature. Pantheism's wide conception of human nature allows for a broad range of ways for people to achieve happiness. There are fewer ways for the Aristotelian or theist to achieve happiness than there are for the pantheist. To the extent that a human being is able to achieve "happiness" by actualising the properties that "define the good of man as such"--they will be leading an intrinsically good life. "Happiness" is then the standard by which to judge the non-derivative (intrinsic) value of a person's life.

Pantheism has a nonanthropocentric conception of human well-being. The human good is characterised partly in terms of relational properties. One must have a certain kind of relation to the Unity in order to live "properly." The set of properties common and unique to humans, which also define the good for humans as such, include relational properties. When a person exemplifies their essential human nature in this way-and it can only be exemplified in this relational way-they are living the "Good" life and can thereby achieve well-being and happiness. This nonanthropocentric conception of human well-being constitutes pantheism's standard of human perfection and virtue. It is a standard of intrinsic value.

As in the case of Aristotle's essentialist conception of the nature of things, the Human Good (defined as it is in terms of human nature) will be different than an animal's good or a plant's good. For the pantheist, the Good of these other things must also be understood partly in terms of their relation to the Unity. Furthermore, the Good associated with various things (humans, plants, etc.) is incommensurable. There is no standard external to each kind of thing by which all things can be measured in terms of perfection, or virtue, or intrinsic value. There is no such thing as intrinsic value *per se* given an essentialist account of the nature's of things which includes essentialist standards of perfection. It is not just wrong to say that a human being is intrinsically more valuable than a tree. It is also nonsense. Of course this does not mean trees should not be used by people.

Taylor (1975) claims that according to the essentialist conception of human nature, the value achieved in human life by fulfilling the standard of intrinsic value is independent its consequences in the lives of others. If this is right then the pantheist will reject any unqualified account of the essentialist's standard of human perfection and virtue. (Indeed, an Aristotelian need not hold such an absolute non-consequentialist account either.) Intrinsic value is, of course, value that is non-derivative. But, what determines the intrinsic goodness in a person's life will, for the pantheist, rely on that person's relationship to the Unity. A person's "good" is partially constituted by the divine Unity of which everything is a part. In pantheistic terms it makes little sense to speak of the intrinsic value of a human life as measured against a standard independent of how that life affects others, since for the pantheist all such value, even so-called "intrinsic value," is partly derivative. The standard of intrinsic value and perfection cannot be determined without reference to the divine Unity. The essential nature and well-being of a person, or anything else, cannot be analysed apart from its context in relation to the Unity and everything it includes.

Although both theism and pantheism have essentialist conceptions of human nature, well-being on either of those accounts cannot be achieved apart from one's relation to others, or the consequences of one's actions for others. And, the pantheist and theist are not the only kind of essentialists for whom consequences and relations matter. For the Aristotelian, in order to achieve well-being it is necessary to

develop a certain kind of character. This requires, in part, certain virtues (e.g. courage, temperance etc.). Since the development and display of character and virtue is connected in significant ways with the consequences of an individual's actions in relation to other people-the concept of one life having "intrinsic value" apart from how it affects any other life is vacuous. Aristotle's account of the virtues makes a practical impossibility of living a "good life" that is fundamentally bad for others. Plato too claims that the virtuous life has its rewards for all. Thus, essentialist conceptions of human nature and the Good need not preclude, and may even entail, an account of persons in relation to other things. For the pantheist, "realising the good for man as man" must be interpreted in terms of the Unity. For pantheism, an essentialist account of human nature does not suggest that there is necessarily only one kind of ideal person or way to achieve happiness.

An essentialist conception of human nature may recognise a range of human natures compatible with "Human Nature" as such. Just as various plants are constituted in such a way that their different requirements must be met if they are to thrive and flourish (i.e. what constitutes their well-being varies), so too will conditions for a person's "well-being" vary from person to person. The pantheist maintains that there is no such thing as an (i.e. one) essential human nature-although some properties are shared. Yet given various human natures, well-being can only be achieved to the extent that the individual satisfies their own nature--achieve their own potential--in their particular circumstances in relation to the Unity. Pantheists eschew hierarchies that have as a criterion for the "good life" any particular intrinsic feature that certain human beings may have which others lack. A good mind used in a good way may help one lead a better life, but so will good looks and a good job.

Pantheists deny personal immortality. There is no life after death in the sense that it is "they" who survive. Historically, the denial of personal immortality is one of pantheism's most distinctive features. This is partly because it is in clear opposition to the theistic view. But, it is primarily significant because it is constitutive of the pantheist's world-view and ethos, and so has implications for pantheistic practice. Believing that one is not going to live again after one dies, just as believing one will live again, has implications for one's choices in this life. There, is of course, nothing like a direct correlation in terms of what one believes concerning immortality and how they choose to live. But for some people, seeing death as the permanent end of one's existence, or alternatively as a prolegomenon to another life, will be a constitutive factor of the ultimate context in which to live. The goals they choose to pursue, the relationships they have, their vocations, may to varying degrees be affected by their belief that death is or is not the permanent end of the individual. The pantheist need not believe that it would be tedious to live forever. They just claim that no one does. This fact is not so much something to be lived with-as to be lived in terms of. The denial of personal immortality is as determinative of how the pantheist lives as the belief in an afterlife is for the theist.

The fact that pantheists (e.g. Spinoza) deny personal immortality is at times given as reason why pantheism is atheistic. The doctrine of immortality is so central to classical Christian theism, that rejecting the former is taken as entailing the denial of the latter. Yet, denying personal immortality can hardly be regarded as grounds for atheism unless theism, with its insistence on personal immortality, is taken to be the only position asserting the existence of a "God" that is not atheistic. The doctrine of personal immortality is not even essential to all forms of theism. Since many theists, e.g. many Jewish theists, deny

immortality, it would seem this denial is neither a necessary nor sufficient condition of atheism.

People who are interested in personal immortality, like people who are not interested (perhaps because they do not believe people survive death) may nevertheless be concerned with their continued existence in an impersonal sense. Impersonal forms of "immortality," or surviving death, can include "surviving" in people's memories, being remembered for one's work, a bone in a reliquary, or becoming another part of the matter/energy cycle once again. One may want to remembered for what one has accomplished, or for the person one was. Impersonal "immortality" may seem to pale next to the theists' insistence on personal immortality and the meeting again of people known in this life. Nevertheless, people's notions of impersonal immortality may be important in various ways. Whether or not they believe in personal immortality, it matters to some people how they will be thought of. No doubt, people who believe in personal immortality are also generally concerned with the impersonal forms. Some may even value being remembered for something they produced as more important than personal survival after death. But typically, the person who believes in personal immortality regards it with a concern that they do not have for various impersonal types of survival.

Some pantheists believe in various types of non-personal immortality (e.g. Spinoza and Robinson Jeffers), and they regard this as significant for reasons other than, or in addition to, the reasons non-pantheists give. They reject the view that personal immortality is more valuable than impersonal immortality. This is not to say that if pantheists believed there was personal immortality they could not regard it as desirable. Perhaps the could even though the idea is anthropocentric and uncongenial to pantheism. But pantheists do not believe in personal immortality, and they regard some types of impersonal immortality as important on distinctively pantheistic grounds.

Robinson Jeffers suggests that what may be important to the pantheist, and regarded as "a kind of salvation," is neither the realisation of the theist's hope for personal immortality, nor the atheists' (or theists') desire to be remembered in certain ways-although the pantheist can desire this as well. Instead, what is distinctively significant is the recognition of the individual as a part of the Unity-what Jeffers calls the "one organic whole ... this one God." The "parts change and pass, or die, people and races and rocks and stars," but the whole remains. He says, "... all its parts are different expressions of the same energy, and they are all in communication with each other, influencing each other, [and are] therefore parts of one organic whole." (See, George Sessions 1977: 481-528). Part of what Jeffers is suggesting is that "salvation" (or immortality) it is not so much a matter of the fact of one's survival in some form; rather, "salvation" consists in the recognition of the "oneness" or Unity of everything. "[T]his whole alone is worthy of the deeper sort of love; and that there is peace, freedom, I might say a kind of salvation, in turning one's affections outward toward this one God, rather than inwards on one's self, or on humanity." This is impersonal rather than personal immortality or salvation, but it is different from the kinds of impersonal survival discussed above. It may even be regarded as a kind of personal salvation, since Jeffers suggests that salvation can be experienced for oneself while alive-and only when alive. Such salvation resembles neither impersonal forms of immortality, nor theists' personal life after death.

Pantheism in Practice

Can pantheists employ traditional modes of theistic and non-theistic practice such as worship, prayer, and meditation? What form might a distinctively pantheistic type of practice take? Pantheists believe in a divine Unity. Yet, in pantheism there is no apparent community of believers organised around their common (though not identical) beliefs by an established body of religious teaching and scripture. Without these traditional constituents of religion pantheists may find themselves wanting to practice their faith-seeking to relate their actions to their beliefs-and yet wondering how to go about it. Pantheists have to ask themselves what they should do given what they believe.

Even if we are not at all clear about what pantheists should do, it may seem we are relatively clear about what they believe. However, if theorists who claim that action sometimes explains belief, or that action and belief must be understood together are right, then it follows that we do not yet know what pantheists believe. Insofar as pantheists lack a distinctive practice, they may be taken not to believe anything (pantheistically) at all. Such theorists claim that systems of belief and practice, if not individual beliefs and practices, are intrinsically related so as to define one another-and they develop together. Therefore, it may not be possible to keep the question of what pantheists believe distinct from the question of what they do. One need not accept such theories to believe, as a matter of commonsense, that belief and practice are connected in such a way that they cannot be adequately understood apart from one another.

In attempting to construct an account of what the contemporary pantheist should do, it would be useful to examine practices that pantheists have traditionally undertaken. But it makes no sense to suppose contemporary pantheists could replicate the representation of social relations that pantheistic rituals might be analysed as having by a symbolist account. If a pantheistic ritual symbolically represents social relations, it represents those of its own society. At any rate, the point is largely moot since the practice of pantheism has never been associated with ritual practice but with a way of life. Thus, Lao Tzu, explicitly eschewed ritual, and Spinoza thought that while ordinary religious practice, ritual etc., was a good idea for the common people since it inculcated valuable ideals, it was beside the point for him. The fact that pantheistic practice has never been associated with ritual may partly explain why pantheism has not been practiced communally in a church.

In literalist or Geertzian terms it makes sense to ask what to do, given certain beliefs, in a way it does not for a symbolist. The kinds of practice suitable to pantheism are explicable in terms of beliefs literally and symbolically understood; and especially (in Geertz's account) in terms of a world view (e.g. belief in a divine Unity) and corresponding ethos. Thus, Lao Tzu describes the *Tao* as a metaphysical reality; as natural law or system of self-regulated principles; and also as a principle, pattern and standard for human conduct. One emulates the *Tao* after discerning its manifest characteristics in the phenomenal world, and to emulate the *Tao* is to practice *Taoism*. In "Song of Myself" Whitman articulates a world view, and evokes the connected ethos he envisages. For Spinoza, examining the nature and implications of Unity (substance) in the *Ethics*, and trying to live in accord with that account, was itself a form of pantheistic practice. Similarly, in writing and living as depicted in "Song of Myself," Whitman practiced the pantheism he preached. The relationship between the thought and practice of Hegel, Plotinus, Bruno etc. is less apparent, but should be of interest to pantheists. If pantheists find any of the various world views and 'ethos' described as consonant with their own, they may pattern their practices after those associated

with such views. In having a particular pantheistic view of the nature of things, certain practices and a way of life must, to an extent, follow.

The idea of looking to religions with pantheistic practices for examples of what to do may seem promising in a literalist or Geertzian approach. Similar kinds of practice should follow similar beliefs. The difficulty is that there seem to be no pantheistic traditions to examine-not even *Taoism*, since as practiced, it is not pantheistic. In traditional religions, practices that might be identifiable as pantheistic are always seen in the context of wider religious (e.g. theistic) practice. In traditions that are partly pantheistic like some native American Indian religions, it is difficult to discern how practices relating to pantheistic beliefs can be distinguished from various kinds of god and spirit worship. Since pantheism has largely been non-communal, individual pantheists, not traditions, must examined.

Religious practice is usually prescribed by teachings and doctrine, and informed by other beliefs widely held among the community of believers. Since there is no widely recognised body of scriptural or other religious teaching in pantheism and never has been (there is little doctrine and no church), there should be little in the way of prescribed practice. As already noted, the philosophical *Taoism* of the *Tao Te Ching* is pantheistic, but it has never been widely practiced and there is no body of ritual associated with it.

The kind of activity undertaken by a believer ideally reflects (i.e. is explainable in terms of) the way in which the religious object, and one's relation to it, is conceived. Differences in practice are the products of varying views on the nature of God and the world-set in the context of a more comprehensive world view. Since pantheistic and theistic accounts of God and the world are best regarded as mutually exclusive, it is likely that the practices of each would be dissimilar. Theistic practice, the intent and so forth, is inappropriate for the pantheist, and *vice versa*. Pantheists will not want to practice in a way that reflects beliefs they do not hold.

If specific pantheistic practices could be identified, these might be adapted to modern pantheism. Yet, to talk of adapting practices in this way is artificial. As a whole, practice neither precedes nor follows the body of beliefs formulated and codified by a religious community. It develops along with them. Even where religious beliefs are taken (e.g. Durkheim) to be rationalisations of practices that precede them, practice occurs in a context of shared conceptions, beliefs and concerns, and are-whether literally or symbolically-expressions of these. Ritual, and religious practice generally, is a product of conscious and unconscious, literal and symbolic, communal religious reflection. Given (and one wonders why) that there has been little structured pantheistic communal reflection, despite the fact that there are many pantheists, there is no identifiable pantheistic practice. There are only identifiable pantheistic world views and beliefs. This does not explain why individual pantheists have not developed recognisable rituals, unless a community of believers (i.e. a church) is necessary for such practices. The practice of pantheism seems confined to individuals acting in ways they see as according with the nature of things.

If contemporary pantheistic ritual exists, it is scarce. (Is the solstice gathering at Stonehenge pantheistic?) The extent to which one can self-consciously set out to construct a ritual is, for reasons already given, suspect. But, given that one can consciously construct symbols that address a community's concerns, there seems no reason why pantheistic rituals cannot be formulated. Indeed, various theistic rituals are self-

consciously created. Furthermore, ritual is only one aspect of religious practice, and pantheists may develop other ways to express their beliefs in action. Since belief and practice are interdependent and evolve together, if some future pantheistic communal reflection results in doctrines, then it is likely to result in practices of various sorts as well. Other than the fact they have lacked what seems to be requisite in terms of a community of pantheists, there may be additional or alternative explanations of why pantheists have not developed rituals. Maybe the lack of community can just as easily be explained by the lack of a developed mode of practice as *vice versa*.

Pantheists basically lack scripture and an established body of doctrine and discourse that could help establish the nature of pantheistic practice. However, it this is not entirely true. The pantheist can, to some extent, rely on traditional religious scripture that is recognisably pantheistic; for example, some *taoist* texts, and some Western and non-Western theistic scripture. Pantheists also have recourse to numerous philosophical sources-Spinoza etc. But, the pantheist is not without alternatives to the scripture and discourse theists have at their disposal. To some extent, the pantheist too will know what to do to practice pantheism. Art, music, literature and poetry, fulfil the same kinds of roles in pantheism as they do in theism. As representations of cultural patterns they reflect and sustain a world view and ethos. In Geertz's (1973: 93) terms they symbolically function as both a model *of* reality and a model *for* reality. "Culture patterns are ‘models’ ... they are sets of symbols whose relations to one another ‘model’ relations among entities, processes or what-have-you ... they give meaning, that is objective conceptual form, to social and psychological reality both by shaping themselves to it and by shaping it to themselves." Pantheists recognise cultural patterns and symbolic representations that "model" their beliefs. Given such beliefs, and the efficacy of symbolic representations of those beliefs; certain other beliefs, actions, and attitudes will be regarded, cognitively and affectively, as appropriate and correct.

In theistic traditions, prayer-which is a type of worship-and sometimes meditation, are the principle forms of religious practice. They are often set in the context of ritual. Theism gives a variety of reasons why prayer and worship are appropriate and necessary forms of theistic practice. But, what about for the pantheist? In principle, pantheists will not do things that literally conflict with the beliefs they express. They will not worship if worship implies the recognition of an independent and superior god, since this theistic belief is antithetical to a central tenet of pantheism. Are prayer and worship appropriate kinds of practice for the pantheist? Given that the pantheist should not pray to or worship a theistic God, can she worship the pantheistic Unity?

Worship and Prayer

Worship and prayer are not suitable to pantheism. It has often been claimed by theists and atheists that pantheistic worship (e.g. worshipping the Unity) is idolatrous. It is worshipping a false god. Unlike the theist or atheist, however, the pantheist believes a divine Unity exists-a kind of god. So pantheists, if they do worship the Unity, reject the idea that they are worshipping a false god. What is wrong with pantheistic worship is not that it is idolatrous, but something more basic having to do with both the nature of worship and Unity. Even if the Unity exists, worshipping it would not be proper pantheistic practice.

Pantheistic worship might naively be thought to be a kind of self-worship; worshipping something of which one is a part or identified with. This too is a mistake. As we have seen, pantheism is not the view that "everything that exists," including oneself, is god; and it is not the view that every particular thing or person is equally god. If worship is not acceptable religious practice for pantheists, it is for reasons other than that such practice involves adoring and venerating (i.e. worshipping) oneself. Worship and prayer are not consonant with pantheism. Like "evil" and "salvation," they are connected to the theistic world-view that pantheists reject. Therefore, except in a highly derivative sense (i.e., derivative from theism) worship and prayer are types of practice that are not acceptable to pantheists. Devotion to the universe, artistic expression, nature observation, etc., are not types of worship as theistically understood-though they may be ways of respecting, honouring, and revering.

What makes worship and prayer inappropriate for the pantheist is not the lack of ontological separation from the Unity that theism claims God has from the world. If there is a sense in which pantheists are ontologically, or in other ways, distinct from the divine Unity, worship and prayer are still inappropriate. If a necessary condition of worship is that it has to be in some significant sense "other regarding," then worship would not on that account be inappropriate to pantheism. What makes it unsuitable is that worship, and especially prayer, are basically directed at "persons"-or at a being with personal characteristics separate and superior to oneself. Whether one's reasons for worship are petitionary or devotional is irrelevant; and so is one's motivation-whether a Freudian way of coping with guilt, or a rationally-based sense of duty. Objects of worship are not oneself, and perhaps not even ontologically distinct from oneself as theism claims, but they are generally taken to be conscious, personal and superior.

Given the nature and goal of worship objects of worship must have a personal character. It might be thought that showing the pantheistic Unity should not, on conceptual grounds, be worshipped is rather uninteresting. That may be right. The implications of this result, however, are anything but insignificant. For the pantheist, the practical consequences of worship and prayer being unavailable as forms of religious practice are enormous.

In the theistic view, worship and prayer are practically synonymous with religious practice. And, even in (theoretically) non-theistic religious traditions such as Buddhism and Taoism, worship and prayer are frequent if not prevalent. Yet, the pantheist is faced with the problem of finding a way to practice pantheism that is consistent with the finding that worship and prayer make sense only in a theistic context. As a result, one of the defining and most noticeable characteristics of pantheism will be the type of practice it takes up. The practices involved, whatever they are, will be different not only from those in theistic traditions, but also from those in non-theistic ones in which theistic practice is so much a part.

Goal: Relationship or State?

Do pantheists seek a relationship with the impersonal Unity rather than a "state"? The choices of the religious objective for the pantheist are either a relationship with the Unity or a state of some kind. The kind of religious practice pantheism (like theism) engenders is a function of the kind of goal sought. What then is the religious objective of pantheism? If there were no such objective to pursue through practice,

the question of how to practice pantheism becomes superfluous. That there is a goal to pursue is intrinsic to the nature of religion.

In pantheistic systems such as Spinoza's or philosophical Taoism, the objective is best described as a state rather than a relation. However, just as theism correctly claims that although the principle goal of theistic practice is a relation to God, this also involves a "state of the individual"; so the pantheist claims that although pantheistic practice is principally concerned with a "state of an individual," a crucial and intrinsic aspect of this state is one's relation to the divine Unity. However, granted that a dichotomy between the objective as "relationship" or "state" is not firm; the principal form of practice-contemplative and meditative on the one hand, or worship on the other-follows from the objective emphasised. In theism it is on a personal relationship to God. In pantheism, the emphasis is on an individual state resulting from an understanding of, and a right relation to, the Unity. Practice will be contemplative and meditative rather than devotional. As in the case of theism, pantheistic practices-like the beliefs they are related to-are meant to have practical consequences both in terms of what one does, and more generally, the way one lives.

The question, of course, is how the pantheist is to arrive at "the right relation" to the Unity thereby achieving their objective. Answering this is the principal focus of both Spinoza's *Ethics*, the *Tao Te Ching* and most other pantheistic literature (e.g. Whitman's "Song of Myself"). What one actually does depends partly on the individual (i.e. Spinoza is no Whitman), and also on the particulars of the state sought. Since the pantheistic conception(s) of reality is ultimately very different from, for example, that of the Theravada Buddhist, there is no reason to suppose the pantheistic objective to be like *nirvana*. The pantheist's relation to the divine Unity does not entail the obliteration of self or liberation that a Buddhist's identification with Brahman does; nor is it like the theistic mystic's union with God. There may be aspects of the state pantheists seek that are similar to Buddhist goals, and even to theistic ones-though to a far lesser extent. But, even if the pantheist's objective is as different from what the Buddhist seeks as it is from what the theist seeks, the means for achieving it remain contemplative or meditative, rather than devotional.

For Spinoza, acquiring the happiness described in the *Ethics*is largely an intellectual achievement. It is difficult to see how one can attain the understanding and identification with "God" that Spinoza claims leads to peace of mind and "blessedness" (i.e., the highest achievement of the individual) without addressing the problem discursively rather than affectively by intuition and meditation-although discursive thinking and these other methods are by no means inconsistent. But even though Spinoza's approach involves little that is not discursive; it is contemplative, and the objective remains primarily a state rather than relation. Worship is not a mode of practice conducive to achieving the state Spinoza seeks. Granted that Spinoza's method is intellectualistic; other approaches are possible-especially where the objective itself is conceived of differently (i.e. less intellectualistic). Spinoza of course recognises that his own method is not suited to most people and acknowledges that ordinary practice such as worship and prayer may at times engender ends he describes. Just as theists use various methods to pursue their objective-some more intellectualistic than others-so in pantheism certain kinds of practices are suited to certain kinds of people. As in other religions, the means by which pantheists pursue their objectives are generally not overtly or overly intellectualised. To do so can undermine practice by upsetting the balance

between the affective and intellectual aspects of their belief system.

The pantheist is likely to view the kinds of goals that most religious traditions envision as excessive and grandiose-as neither believable nor desirable. What is more, although they are not humanists, like humanists pantheists are likely to view those objectives and related beliefs much as theistic traditions viewed those of "primitive religions" and of each other: as superstitiously anthropocentric and so capable of being naturalistically explained. The state sought by the pantheist supervenes (as in Taoism) on establishing the right relation with the Unity by means of cultivating a life suited to the nature of the Unity and of oneself. But for the pantheist this is a goal in itself, a this-worldly happiness. The pantheist eschews a notion of their being further goals; for example, the theist's beatific vision; personal immortality; *nirvana;* and even Spinoza's "blessedness," interpreted as something other-worldly.

The pantheist's happiness is nevertheless a special "state" that is difficult to achieve. Being a kind of utopian ideal it too is perhaps grandiose. Ordinary happiness is part of it but should not be conflated with the kind of thoroughgoing happiness the pantheist thinks it is possible to attain now and again. Much as Kierkegaard denied that "truth," "subjectivity" and even "immortality" are attainable once and for all, the pantheists denies their objective is a once and for all achievement. It is a state of well-being that involves a sustained peace of mind and the kind of happiness that comes from, or is identical with, such a state of mind. Since one's own state of mind and relation to the all-inclusive Unity are partly dependent upon other people and things, the state the pantheist seeks is not something achievable in isolation. Pantheism involves a this-worldly utopian vision based on individual's relations to, and identification with, the Unity.

"Nature"-which appears to be equated with the "Great Outdoors"-has pride of place in a pantheistic world view and ethos. It is assumed that pantheists are nature lovers, if not nature mystics. This view of pantheists as naturalists and rural outdoor people as opposed to city dwellers, is common. A reason for the pantheist's stress on Nature is that anthropocentricism is seen as incompatible with a proper recognition of Unity. It is seen as undermining the cosmocentric perspective required by pantheistic ethics, and a pantheistic way of life; as antithetical to the pantheist world view and ethos. Involvement in nature de-emphasises the anthropocentrism pantheism believes endemic to theism and detrimental to well-being and Unity.

This characterisation of pantheists as loving nature and as having to establish a relationship to things natural is what principally informs vague views as to how pantheism is to be practiced-especially among contemporary pantheists. Practice becomes an expression of a love of nature-usually by "communing" with it. It is no wonder pantheism is often regarded as little more than a type of nature mysticism. But for the pantheist, "love" of nature is expressed primarily in ethical rather than in mystical or quasi-mystical terms. Pantheistic ethics focuses on how to live and on the individual's relation to the natural order-an order of which others are a part. One's own well-being and that of others depends on it. Since nature is taken as intrinsically valuable, and because relating appropriately to nature presupposes its preservation and protection; nature in general and environmental issues in particular, are important to the pantheist. Like many others, pantheists see their well-being as intrinsically connected to the wider environment as well as to things more immediate (e.g. employment).

Is the urban person at a *religious* disadvantage from a pantheistic perspective? Without denying the significance Nature has for the pantheist (e.g., as a standard of behaviour, and as an object of meditation conducive to a "right" state of mind), is there reason to believe a pantheist who prefers an urban to a pastoral setting, and who likes technology, is risking spiritual depravity? Does the pantheist have a duty to spend time in natural settings if they prefer the city? Technology is associated with the Urban, and the pantheist may see much of it, or too much of it, as inimical to Unity and well-being. Technology is devalued when it is taken as undermining the kinds of value pantheism seeks to promote. Technology (people using it) despoils the environment. At any rate, since the world is increasingly urban, for pantheism to be viable it will have to be possible to practice it in cities.

A person who prefers city street life may claim there is a bias towards the non-human in a pantheist's exclusive insistence on Nature. Why cannot cities-themselves "natural" in a way-also be conducive to the practice of pantheism? Perhaps cities could be if they and many of their people were not as neglected and abused as much as some wilderness areas (if the comparison makes any sense). "God's country" for the pantheist denotes urban as well as pastoral settings-indeed it extends to the suburbs. Given the existence of a divine Unity one should not regard all personal preferences (e.g., for a garden), as cosmically endorsed. If the goal of pantheism is a way of life and a kind of "state," then any locale that is generally conducive to promoting those goals is acceptable. This may have more to do with the kind of urban or rural setting one lives in rather than just whether the setting is urban or rural.

In terms of its practice, one of the striking things about pantheism is that it has not produced a church or any kind of organisation engaged in overseeing its practice. Apparently a community of pantheists is not necessary for the practice of pantheism. Either this is an historical accident, or it has to do with structural features of pantheism. Pantheists, like many theists, tend to regard Churches and religious leaders with suspicion. The kind of orientation that the pantheist seeks vis a vis the Unity is not taken to be something a church can facilitate. The mediation churches provide is seen as superfluous or harmful-just as it has been by many mystics. Organised religions are seen as divisive and exclusivist, and churches perhaps are seen as essentially anthropocentric. It is for these kinds of reasons that there never has been a pantheistic church and probably never will be.

Pantheism remains a fertile subject for natural theology. Natural theologians have hardly approached it. Pantheism should be of interest to those in the philosophy of religion who seek a way out of the constrictions (often institutional ones) put upon them by working within the confines of classical theism; especially as the issues relating to classical theism have been taken up by the contemporary christian conservative analytic philosophers of religion. Perhaps pantheism will be of most interest to those who do not believe in a theistic God, yet are concerned with many of the traditional questions that natural theologians have always asked, and that religious traditions necessarily address.

Pantheism's lack of "success" in worldly terms on the religion market may have to do with the fact that it is antithetical to any power structure; the kind, for example, found in the Catholic church. If so, then even though pantheism may be more profoundly religious than institutionalised religions, it may be doomed to ineffectiveness because it cannot manipulate power-it cannot "play the game." Wielding various kinds of power has been a feature of religion from its most "primitive" to its most sophisticated levels-a feature

churches can generally not control. Pantheism negates the power struggle through its emphasis on Unity. It refuses to see religion in political and hierarchical terms. Pantheism is the religion that tries most completely to escape the limitations created by anthropocentric models of religion that create god in man's image.

Benjamin Peirce

Benjamin Peirce (b. April 4, 1809, d. October 6, 1880) was a professor at Harvard with interests in celestial mechanics, applications of plane and spherical trigonometry to navigation, number theory and algebra. In mechanics, he helped to establish the (effects of the) orbit of Neptune (in relation to Uranus). In number theory, he proved that there is no odd perfect number with fewer than four distinct prime factors. In algebra, he published a comprehensive book on complex associative algebras. Peirce is also of interest to philosophers because of his remarks about the nature and necessity of mathematics.

1. Career

Born in 1809, Peirce became a major figure in mathematics and the physical sciences during a period when the U.S. was still a minor country in these areas (Hogan 1991). A student at Harvard College, he was appointed tutor there in 1829. Two years later he became Professor of Mathematics in the University, a post which was changed in 1842 to cover astronomy also; he held it until his death in 1880. He played a prominent role in the development of the science curriculum of the university, and also acted as College librarian for a time. However, he was not a successful teacher, being impatient with students lacking strong gifts; but he wrote some introductory textbooks in mathematics, and also a more advanced one in mechanics (Peirce 1855). Among his other appointments, the most important one was Director of the U.S. Coast Survey from 1867 to 1874. Peirce also exercised influence through his children. By far the most prominent was Charles Sanders Peirce (1839-1914), who became a remarkable though maverick polymath, as mathematician, chemist, logician, historian, and many other activities. In addition, James Mills (1834-1906) became in turn professor of mathematics at Harvard, Benjamin Mills (1844-1870) a mining engineer, and Herbert Henry Davis (1849-1916) a diplomat. However, Harvard professor

Benjamin Osgood Peirce (1854-1914), mathematician and physicist, was not a relative. Benjamin Peirce did not think of himself as a philosopher in any academic sense, yet his work manifests interests of this kind, in two different ways. The first was related to his teaching.

2. Mathematics, mechanics and God

To a degree unusually explicit in a mathematician of that time Peirce affirmed his Christianity, seeing mathematics as study of God's work by God's creatures. He rarely committed such sentiments to print; but a short passage occurs in the textbook on mechanics previously mentioned, when considering the idea that the occurrence of perpetual motion in nature

> would have proved destructive to human belief, in the spiritual origin of force and the necessity of a First Cause superior to matter, and would have subjected the grand plans of Divine benevolence to the will and caprice of man (Peirce 1855, 31).

Peirce was more direct in a course of Lowell Lectures on ‘Ideality in the physical sciences’ delivered at Harvard in 1879, which James Peirce edited for posthumous publication (Peirce 1881b). ‘Ideality’ connoted ‘ideal-ism’ as evident in certain knowledge, ‘pre-eminently the foundation of the mathematics’. His detailed account concentrated almost entirely upon cosmology and cosmogony with some geology (Petersen 1955). He did not argue for his stance beyond some claims for existence by design.

3. Algebras and their philosophy

Peirce was primarily an algebraist in his mathematical style; for example, he was enthusiastic for the cause of quaternions in mechanics after their introduction by W. R. Hamilton in the mid 1840s, and of the various traditions in mechanics he showed some favour for the ‘analytical’ approach, where this adjective refers to the links to algebra. His best remembered publication was a treatment of ‘linear associative algebras’, that is, all algebras in which the associative law $x(yz)=(xy)z$ was upheld. ‘Linear’ did not carry the connotation of matrix theory, which was still being born in others' hands, but referred to the form of linear combination, such as:

$$q = a + bi + cj + dk$$

in the case of a quaternion q. Peirce wrote an extensive survey (Peirce 1870), determining the numbers of all algebras with from two to six elements obeying also various other laws (Walsh 2000, ch. 2). To two of those he gave names which have become durable: ‘idempotent’, the law $x^m = x$ (for $m \geq 2$) which George Boole had introduced in this form in his algebra of logic in 1847; and ‘nilpotent’, when $x^m = 0$, for some m. The history of the publication of this work is very unusual (Grattan-Guinness 1997). Peirce had presented some of his results from 1867 onwards to the National Academy of Sciences, of which he had been appointed a founder member four years earlier; but they could not afford to print it. Thus, in an

initiative taken by Coast Survey staff, a lady without mathematical training but possessing a fine hand was found who could both read his ghastly script and write out the entire text 12 pages at a time on lithograph stones. 100 copies were printed (Peirce 1870), and distributed world-wide to major mathematicians and professional colleagues. Eleven years later Charles, then at Johns Hopkins University, had the lithograph reprinted posthumously, with some additional notes of his own, as a long paper in American journal of mathematics, which J.J. Sylvester had recently launched (Peirce 1881a); it also came out in book form in the next year. This study helped mathematicians to recognise an aspect of the wide variety of algebras which could be examined; it also played a role in the development of model theory in the U.S. in the early 1900s. Enough work on it had been done by then for a book-length study to be written (Shaw 1907).

4. The philosophy of necessity

Peirce seems to have upheld his theological stance for all mathematics, and a little sign is evident in the dedication at its head:

> To my friends This work has been the pleasantest mathematical effort of my life. In no other have I seemed to myself to have received so full a reward for my mental labor in the novelty and breadth of the results. I presume that to the uninitiated the formulae will appear cold and cheerless. But let it be remembered that, like other mathematical formulae, they find their origin in the divine source of all geometry. Whether I shall have the satisfaction of taking part in their exposition, or whether that will remain for some more profound expositer, will be seen in the future (Peirce 1870, 1).

Peirce began with a philosophical statement of a different kind about mathematics which has become his best remembered single statement "Mathematics is the science that draws necessary conclusions" (Peirce 1870, p. 1). What does ‘necessary’ denote? Perhaps he was following a tradition in algebra, upheld especially by Britons such as George Peacock and Augustus De Morgan (a recipient of the lithograph), of distinguishing the ‘form’ of an algebra from its ‘matter’ (that is, an interpretation or application to a given mathematical and/or physical situation) and claiming that its form alone would deliver the consequences from the premises. In his first draft of his text he wrote the rather more comprehensible "Mathematics is the science that draws inferences", and in the second draft "Mathematics is the science that draws consequences", though the last word was altered to yield the enigmatic form involving ‘necessary’ used in the book. The change is not just verbal; he must have realised that the earlier forms were not sufficient (they are satisfied by other sciences, for example), and so added the crucial adjective. Certainly no whiff of modal logic was in his air. His statement appears in the mathematical literature fairly often, but usually without explanation. One feature is clear, but often is not stressed. In all versions Peirce always used the active verb ‘draws’: mathematics was concerned with the act of drawing conclusions, not with the theory of so acting, which belonged in disciplines such as logic. He continued:

> Mathematics, as here defined, belongs to every enquiry; moral as well as physical. Even the rules of logic, by which it is rigidly bound could not be deduced without its aid (Peirce

> 1870, 3).

In a lecture of the late 1870s he described his definition as

> wider than the ordinary definitions. It is subjective; they are objective. This will include knowledge in all lines of research. Under this definition mathematics applies to every mode of enquiry (Peirce 1880, 377).

Thus Peirce maintained the position asserted by Boole that mathematics could be used to analyse logic, not the vice versa relationship between the two disciplines that Gottlob Frege was about to put forward for arithmetic, and which Bertrand Russell was optimistically to claim for *all* mathematics during the 1900s. Curiously, the third draft of the lithograph contains this contrary stance in "Mathematics, as here defined, belongs to every enquiry; it is even a portion of deductive logic, to the laws of which it is rigidly subject"; but by completion he had changed his mind. Peirce's son Charles claimed to have influenced his father in forming his definitive position, and fiercely upheld it himself; thereby he helped to forge a wide division between the algebraic logic which he was developing from the early 1870s with his father, Boole and de Morgan as chief formative influences, and the logicism (as it became called later) of Frege and Russell and also the ‘mathematical logic’ of Giuseppe Peano and his school in Turin (Grattan-Guinness 1988).

Historicist Theories of Rationality

Of those philosophers who have attempted to characterize scientific rationality, most have attended in some way to the history of science. Even Karl Popper, who is hardly a historicist by anyone's standards, frequently employs the history of science as an illustrative and polemical device. However, relatively few theorists have offered theories according to which data drawn from the history of science somehow *constitute* or *are evidential for* the concept of rationality. Let us call such theories historicist theories.

Roughly put, the idea behind historicist theories of rationality is that a good theory of rationality should somehow fit the history of science. According to a minimal reading of "fit", a good theory of rationality will label as rational most of the major episodes in the history of science. A more demanding reading asserts that the best theory of rationality is the one that maximizes the number of rational episodes in the history of science (subject to some filtering out of some sociologically infected episodes). However, it is unclear whether (i)historicism is a conceptual claim according to which it is an analytic or at least necessary truth that rationality fit history, or (ii)whether historicism is an epistemological claim according to which the best way to find out about rationality is to consult the history of science. Historicism (i) seems unmotivated, while historicism (ii) might descend into triviality. For instance, in the case of instrumental rules which tell us the best way to achieve certain goals, philosophers of all stripes would say that looking at historical attempts to achieve those goals will help us evaluate our current proposals for achieving them. Another ambiguity in historicism concerns its scope. Does historicism become a good idea only once one has established that science is basically successful, or should historicism be endorsed within every scientific community and possible world?

In order to understand historicism, one must also understand the distinction between methodology and meta-methodology. In the parlance of the history and philosophy of science, a methodology for scientific rationality is a theory of rationality: it tells us what is rational and what is not in specific cases. Thus, the rule "Always accept the theory with the greatest degree of confirmation" would count as (part of) a methodology. On the other hand, a meta-methodology provides us with the standards by which be evaluate the theories of rationality which constitute our methodologies. To be a historicist about rationality is to accept a meta-methodological claim: a good theory of rationality must fit the history of science. Thus although historicists might agree on a general meta-methodology, they can and do vary widely in the sort of theory that they produce using that meta- methodology. To acquire a feel for the general approach, let us first review the work of the three major historicists, Thomas Kuhn, Imre Lakatos and Larry Laudan.

- Kuhn

Kuhn

Historicism in the philosophy of science is a fairly recent development. It can perhaps be dated to the publication of Kuhn's influential *The Structure of Scientific Revolutions* in 1962, Before that point, the two dominant theories of rationality were confirmationism (scientists should accept theories that are probably true, given the evidence) and falsificationism (scientists should reject theories that make false predictions about observables and replace them with theories that conform to all available evidence). Each of these theories springs from purely logical roots, confirmationism from Carnap's work on inductive logic, and falsificationism from Popper's rejection of inductive logic coupled with his assertion that universals can be falsified by a single counter-instance. Neither of these theories was accountable to the history of science in the following important sense:. If it turned out that the history of science exemplified few or no decisions in accordance with, say, Carnap's confirmationism, then so much the worse for the history of science. Such a discovery would merely show that scientists were largely irrational. It would not challenge confirmationism. Rather, confirmationism was mainly challenged on conceptual, ahistorical grounds, such as its inability to generate plausible yet non-arbitrary levels of confirmation for moderately sized samples, the difficulties encountered in devising a suitable criterion for evidential relevance, and so on.

Kuhn's work effected three major transformations in the study of scientific rationality. First, and most importantly, it brought history to the fore. The implicit (if not explicit) message of *The Structure of Scientific Revolutions* is that a respectable theory of *rational* scientific procedure must conform to the greater part of *actual* scientific procedure. Second, instead of focussing on the theory as the unit of rational exchange, *Structure* was based on a unit that could persist through minor theoretical changes. In so doing, it could distinguish between revisions and wholesale rejection. Kuhn called this unit "the paradigm", and its ancestors live on as the research programme, the research tradition, the global theoretical unit, and so on. Third, Kuhn's work highlighted the real problems that historically aware accounts of rationality face: when all is said and done, there may be no trans-historical rule for rational scientific procedure.

Before dealing with specifics, it is important to stress that one should approach the exegetical details of Kuhn's account with great trepidation. Many different interpretations exist, perhaps because the internal consistency of Kuhn's positions still stands in some doubt. Thus what follows is no doubt too quick and

would be regarded by some as fundamentally inaccurate. Those who are especially interested in Kuhnian hermeneutics are encouraged to consult Hoyningen-Huene (1993). As an example of the exegetical problems which confront the reader at every turn, there is considerable disagreement over the proper interpretation of the word "paradigm", At one extreme is a very narrow interpretation according to which a paradigm consists of a set of exemplars, where an exemplar can be a famous solved problem, a textbook, or a famous experiment. At the other extreme a paradigm consists of an entire theoretical worldview, represented by an ontology, a set of laws, a list of methodological prescriptions, and a set of fundamental values for science. According to a third reading, which is orthogonal to the others, a paradigm is a fundamentally sociological entity , individuated and constituted by patterns of education and alliances. To maximize the sense of the following account, it is best to choose a fairly wide sense of the term.

According to Kuhn, scientific practice is divided into two phases, called *normal* science and *revolutionary* science. During normal science, the dominant paradigm is neither questioned nor seriously tested. Rather, the members of the scientific community employ the paradigm as a tool for solving outstanding problems. Occasionally, the community will encounter especially resistant problems, or anomalies, but a small number of these problems will occasion little anxiety. Only as the anomalies accumulate will the community pass into a state of crisis, which may push it into the phase of revolutionary science.

During a period of revolutionary science, the scientific community actively debates the underlying principles of the dominant paradigm and its rivals. Thus, the business- as-usual of routine problem solving is suspended until a new paradigm (or perhaps the old one) establishes dominance. The way in which dominance is established is perhaps the most important locus of disagreement concerning Kuhn's work. The most influential interpretation (one which Kuhn has spent much time disavowing) paints Kuhn as an arationalist. This interpretation makes much of Kuhn's use of the theory-ladenness of observation and various sorts of incommensurability. The supposed result of these features is that the proponents of different paradigms will often be unable to communicate with each other, and that even when they can communicate, their standards of assessment will always favor their own paradigms. Thus, there is no rational basis for choosing between paradigms: the switch from one worldview to another is not so much a reasoned matter as the scientific equivalent of a perceptual gestalt shift. On this view, the transition between paradigms is best explained sociologically, in terms of institutional might, polemics and perhaps generational replacement.

The previous argument requires very strong, possibly unrealistically strong senses of incommensurability and theory- ladenness. The more moderate view of revolutionary science does not presuppose that paradigms are separated by unbridgeable linguistic gaps. However, it does retain incommensurability about values. On this view, scientists are trained to reach a rational consensus *in the absence of rules for doing so*. Rationality can no longer be procedurally flow-charted. This interpretation of Kuhn is often coupled with the claim that science has progressed in light of its increasing ability to solve problems. Again, though, there is an important qualification: while we can claim that, e.g., the Newtonian paradigm solved more problems than the Aristotelian one, we cannot claim that Aristotelian set of solved problems is included in the Newtonian one. The transitions from one paradigm to another involves some losses as

well as gains, but on balance, there is a net gain in problem solving ability.

Although this interpretation of Kuhn paints him as a rationalist, it posits a form of rationalism that rejects two claims that many rationalists had thought essential to their enterprise: (i)that rationality is a rule-governed process, and (ii)that scientific progress is cumulative. The reasons for these two claims are not so much historical as conceptual. For instance, if we suppose that the choice between paradigms is made in the absence of rules, and that we should trust it as rational simply because the people making the choices are properly trained, then might we not wonder whether a purely sociological explanation is in order? Similarly, if one paradigm is held to solve more problems than another, even in the presence of important problems solved by the second paradigm but not by the first, then might we not wonder whether the apparent progress is no more than a case of history re-written by the victors. What solid philosophical grounds are there for holding that the gains achieved by the victorious paradigm outweigh the losses? Among others, Brown (1985) addresses the first worry and Laudan (1977) the second (as will be discussed later in this entry), but, to date there has been no satisfactory answer to any of these questions. Thus, Kuhn the rationalist seems to stand on shaky conceptual ground.

Specific worries aside, Kuhn is unsatisfactory for our purposes because he provides us with neither a specific account of rationality nor an explicit account of historicist meta- methodology. Because they are specific where Kuhn is not, Kuhn's main successors, Imre Lakatos and Larry Laudan deserve our special attention.

Lakatos

Lakatos's theory of rationality is based on the idea of the research programme, which is a sequence of theories characterized by a *hard-core* (the features of the theories that are essential for membership in the research programme), the *protective belt* (the features that may be altered), the *negative heuristic* (an injunction not to change the hard core), and the *positive heuristic* (a plan for modifying the protective belt). The protective belt is altered for two reasons. In its early stages, a research programme will make unrealistic assumptions (i.e. Newton's early assumption that the sun and the earth are point masses). The protective belt is altered in order to make the programme more realistic. It becomes testable only when it has achieved a sufficient degree of realism. Once the programme has reached the phase of testability, the protective belt is altered when the programme makes false experimental predictions.

However, not all alterations to the protective belt are equal. If an alteration not only fixes the problem at hand but also allows the research programme to make a *novel prediction*, then the alteration is said to be progressive. If the alteration is no more than an ad hoc manoeuvre, that is, if it does not lead to any novel predictions, then it is regarded as *degenerate*. Initially Lakatos classifies a prediction as novel if and only if the phenomenon being predicted has never been observed prior to the prediction. Later Lakatos (Lakatos and Zahar, 1976) extends the definition to cover phenomena that may have been observed before the time of prediction but which were not among the problems which the alteration was designed to solve.

A research programme is in good health as long as a sufficient number of the alterations to it are progressive. Its troubles multiply to the extent that these alterations are degenerate. Once a research programme is sufficiently degenerate, and once there is a progressive research programme to take its place, the degenerate programme should be jettisoned. However, Lakatos does not provide us with details concerning ways to measure degeneracy, nor does he locate the point at which degeneracy can prove fatal to a research programme.

Lakatos's meta-methodology is interesting precisely because it matches his methodology: a meta-methodological research programme in the philosophy of science is progressive as long as it continues to make novel predictions. This may seem puzzling. What predictions can a theory of rationality make? Lakatos's answer is that the predictions concern basic value judgments made by scientists at the time concerning the rationality and irrationality of certain episodes. To see this, suppose that, according to Lakatos's theory, a certain research programme of the past became unacceptably degenerate at a certain time. Subsequent historical investigation might uncover documents which attest to the attitudes of the scientific community at the time. Suppose that these documents show that the community was preparing to reject the research programme in question. In this case, we would say that Lakatos's theory had made a successful novel prediction.

One could easily question the weight that Lakatos places on novel predictions, both at the methodological and meta-methodological levels. Lakatos faces the following dilemma. The attainment of novel predictions is either valuable in and of itself or it is valuable as a way of achieving some other goal. If Lakatos claims that novel predictions are especially valuable in and of themselves then he faces a quite justified charge of arbitrariness. If he says that they are valuable for their use in achieving other goals then he must say what those goals are and demonstrate that novel predictions are expecially useful in achieving them. For instance, suppose Lakatos were to say that the pursuit of novel predictions provides us with the best and fastest way of increasing the observable content of our theories. Were he to say this he would need to provide us with a viable notion of and metric for observable content. In particular he would have to tell us what it is for one theory to have more observable content than another. If he presupposes some sort of cumulativity principle (i.e. that the better theory says everything true about observables that the worse one did plus a little bit more) than his theory is historically implausible. If he denies cumulativity, then the problem he faces, i.e. that of providing a sound basis for observational content, has foiled all who have tried to solve it.

Laudan

In *Progress and Its Problems,* Larry Laudan presents both an explicit meta-methodology and a normative theory of rationality. According to his meta-methodology, a successful theory of rationality should respect "our preferred pre-analytic intuitions about scientific rationality". (Laudan 1977 160) These intuitions consist of judgments of the rationality of certain explicit cases, (e.g., "it was rational to accept Newtonian mechanics and to reject Aristotelian mechanics by, say, 1800", and "it was irrational after 1830 to accept the biblical chronology as a literal account of earth history"). Thus, although not every episode in the history of science is represented in Laudan's meta-methodology, a subset of it is, where

this subset consists of the "obvious" cases.

The theory of rationality supposedly generated by Laudan's methodology is centered on the notion of the research tradition. Laudan's research traditions somewhat resemble Kuhn's paradigms and Lakatos's research programmes. Like Kuhn's paradigms (on the wider reading of the term) research traditions contain both metaphysical and methodological elements. However, Laudan downplays the sociological and pedagogical elements (e.g. training networks and exemplars) that are so important to Kuhn. Like Lakatos's paradigms, the theories generated by a research tradition will change through time, but, where Lakatos's research programmes are defined as a sequence of theories, the theories do not themselves constitute the research tradition. Laudan also claims that the research tradition is a much less rigid concept than the Lakatosian research programme, which is based on an inflexible hard-core.

However, Laudan radically differentiates himself from Kuhn and Lakatos in his accounts of scientific progress and rationality. He claims that there are two sorts of problems that face every research tradition, empirical problems (akin to Kuhnian anomalies) and conceptual problems (i.e. problems of consistency, either internal or with dominant traditions in other fields). We should *accept* the research tradition that has solved the most problems and *pursue* the tradition that is currently solving problems at the greatest rate. Science progresses by solving more problems. However, Laudan does not presume cumulativity: although a given current research tradition will have solved more problems than its predecessors, there may be particular problems that have become "unsolved" by the current tradition. Thus, unlike Kuhn, Laudan believes that there is a simple concept which serves as a basis for both progress and rationality. Unlike Lakatos, Laudan (i)rejects both the idea of empirical content and the cumulative growth of theories and (ii)places no extra value on the concept of a novel prediction, and no great disvalue on ad hocness.

As appealing as it may seem, Laudan's theory of rationality faces some potentially fatal criticisms. First, how do we determine which research tradition has solved the most problems. Is the "problem of the planets" to be counted as one problem or nine? There is no reason to believe that the enumeration and/or weighting of problems is not relative to research tradition. Laudan offers us no grounds for faith here, since he wants his theory to be robust even in the presence of a strong degree of incommensurability. Without a common scheme of enumeration and/or weighting Laudan's theory may lead to ambiguous results, according to which the rational tradition to pursue depends on who is doing the counting. Second, although Laudan takes some pains in differentiating research traditions from paradigms and research programmes, the notion of a research tradition is still somewhat fuzzy. As with paradigms and programmes, the fuzziness is especially apparent at the level of historical application.

An independent set of problems concerns Laudan's meta-methodology and its link to his theory of rationality. First, since Laudan takes his theory of rationality to apply to all spheres of intellectual endeavor, including the philosophy of science, we should expect his meta-methodology (i.e., his criterion regulating the rational choice of a theory of scientific rationality) to be identical with his theory of rationality. Yet the two are very different. His meta-methodology is a foundational fit-the-data affair, while the ground-level criterion rejects the existence of data in he foundationalist sense. Now, Laudan could retract the claim that his theory of rationality has applicability outside of science, but as we shall

see later, that would lead him into serious problems. Second, Laudan's list of 7 pre-analytic intuitions is fairly uncontroversial. But, we may ask why we believe it to be uncontroversial. Is it because we have all been socially conditioned in the same way.? Or, is it because we have a prior criterion of rationality, according to which we judge the "intuitive" cases? If the former, then there is no reason to privilege our pre-analytic intuitions. If the latter, then, rather than consulting the history of science, we should merely try to explicate our prior criterion. Either way, an approach based on intuitions faces severe difficulties. Third, even if we could provide a firm philosophical basis for this approach, we would have very little data to go on. Laudan cites only seven data points. Without doubt, many theories of rationality, some plausible and some not, would fit these data points. For instance, consider the following criterion:

> An episode in the history of science is rational if and only if it is one of the following episodes: {here follows the list of paradigmatically rational episodes}; and an episode in the history of science is irrational if and only if it is one of the following episodes: {here follows the list of paradigmatically irrational episodes}. All other episodes are neither rational nor irrational.

Clearly this is a silly criterion, but it meets Laudan's meta- methodological constraints. Laudan differentiates his methodology from his meta-methodology to avoid circular and/or self- supporting means of testing a methodology. Circularity is probably not a worry. Laudan probably would do better by equating his methodology with his meta-methodology. At any rate, Laudan himself has disavowed historicism (e.g., Laudan 1986), although for somewhat suspect reasons.

General Criticisms

Specifics aside, there are a number of important issues that have yet to be satisfactorily addressed by historicist theories of rationality. (1) What precisely is a historicist theory of rationality supposed to accomplish? According to Lakatos, one is rational as long as one avoids ad hocness as much as possible; according to Laudan, one is rational as long as one accepts the research tradition that has solved the most problems and pursues the one that is solving them at the greatest rate. Yet neither writer stipulates that rational agents must have the avoidance of ad hocness or the maximization of solved problems in mind as they go about their scientific business. As long as their theoretical behavior is in accord with the Lakatosian/Laudanian dicta, they are rational, regardless of their conscious motivations.

Let us call theories of rationality which evaluate agents on the basis of their theoretical choices and not on the basis of the reasons for the choices *externalist* theories. Externalist theories are wider than internalist (motive based) ones in an important way: the right choice made for the wrong reasons is rational according to externalism. Since Lakatos and Laudan want their theories of rationality to cover most of the history of science, and since the conscious motivations of scientists do seem to have changed over time, it seems that these writers are locked into externalism.

However, upon further examination externalist theories of rationality are very puzzling. Let us compare them with another form of epistemic externalism, an externalist theory of perception. According to such

theories, whether one is justified depends only on whether one's perceptual belief was produced by a reliable mechanism or process. One need not be conscious of a description or justification of that process. Now, in the perceptual case, we have a general idea of the nature of the process and every reason to trust in its reliability (dreamer arguments aside). The problem with externalist theories of rationality, on the other hand, is that we have no idea of the mechanism that would make a scientist, act in such a way that she minimized ad hocness even though her actual intentions were directed towards some other cognitive goal. Where externalist theories of perception depend on tangible information provided by the psychology of perception, externalist theories of rationality depend on a very mysterious invisible hand. Until the workings of that hand are made visible, we should be very suspicious of externalist theories of rationality.

(2)Historicist theories of rationality are also much more difficult to *apply* than their proponents let on. Because the historicist unit of exchange (the paradigm, research programme, research tradition) has much looser conditions of individuation than the single theory, the question of how to group theories into their respective paradigms, etc. can be a difficult one. For instance, Copernicus's theory shared much of Aristotle's physics, Aristotle's commitment to spherical motion and his use of aethereal spheres, Kepler's geo-centrism (almost) and Ptolemy's use of epicycles. In grouping Copernicus with Kepler and Newton, we say that his geocentrism is more important than his beliefs about the way in which things in the heaven moved. There may be reasons for deciding upon this grouping, but the choice is not an automatic one. Since the actual scientists at the time did not think in terms of paradigms, etc., we are not going to be able to make the choice on the basis of historical information. More needs to be said about the standards for such decisions.

A related problem concerns the notion of the *acceptance* of a paradigm, research programme or research tradition. Does the acceptance of a programme involve the literal belief in its truth by every single person in the scientific community? Does it require a general belief in its usefulness? These questions have practical correlates. Was the Copernican system accepted by the time that most astronomer used the Copernican tables, despite their explicit allegiance to an Aristotelian/Ptolemaic cosmology? When it was widely taught in universities? Is quantum mechanics now accepted despite the fact that very few physicists think that it can paint an accurate picture of micro-reality? The question of acceptance has two dimensions. The first concerns what it is for a single person to accept a paradigm, etc. The second concerns the weight of individual acceptance required for community acceptance. Since the data for historicist theories consists of matters of acceptance and rejection at the community level, historicists must provide a great deal more information here before their theories can be applied to the historical record.

(3)What *motivates* us to adopt a historicist theory? One possible motivation comes from our faith in science. To reject historicism is "to claim..., that it is entirely possible that all actual scientific practice, past and present, is irrational and ‘unscientific’, which is in turn to accept the (I think) absurd further consequence that scientists might be bad at doing science". (Brown 1989, 98) However, there are several problems with this motivation. First, our faith in the rationality of science may be more an *a posteriori* matter than an a priori. That is, our faith in science is not blind. We have faith in our science because we have seen what it has accomplished: given our evidence from the history of science, it would be absurd

to conclude that science was not rational. Here, we see that the history of science is rational because it meets our (proto) criteria for progress and rationality. However, in other, counterfactual cases, we would not immediately conclude that scientific practice was rational. For instance, it is not true at every possible world that there is a conceptual link between scientific practice and scientific rationality. Thus, on this view, the history of science is illustrative (and not constitutive) of rationality.

Another problem with the faith-in-science motivation that it is much too weak for many forms of historicism. Our faith in science might lead us to believe that science is not completely irrational, or that it is more rational than not. However, some historicist theories (e.g., some readings of Lakatos, Brown (1989)) claim that the best theory of rationality is the one that, subject to certain conditions, *maximizes* the number of rational episodes in the history of science. General faith in science cannot prop up these maximizing theories.

The second motivation for historicism is due to a form of naturalism. If we reject the idea that epistemology is an *a priori* enterprise and accept that it is merely a form of science, as naturalists tend to do, then historicism might seem tempting. Scientific theories succeed insofar as they fit the data. The data for a *scientific* theory of scientific rationality, if it is to be found anywhere, should be drawn from the history of science. Hence historicism. Leave aside the sloppiness of the preceding argument. Even taken on its own terms, it depends on a simplistic view of the role of theoretical concepts within naturalism. Suppose we endorse naturalism. We can consequently treat rationality as a theoretical posit, much like electrons, viruses and the other theoretical posits of science. Those posits are not justified on the basis of a simple fit-the- data approach. It's difficult to see how they could even play such a role. Rather, they are accepted because they are essential parts of our best explanations for relevant phenomena. The test for a theory of rationality, then, should be this: the best theory of rationality is the one that best explains the data in the history and current practice of science. Simple matters of curve-fitting and maximization should be left aside.

However, if we take this explanationist approach to rationality, then most historicist theories seem irrelevant. None of them explain very much at all. Indeed, the Strong Programme (Bloor 1976) in the sociology of knowledge has argued that rationality plays no explanatory role whatsoever. No doubt, the arguments of the Strong Programme are at least slightly overblown, but they do show that once one moves to an explanationist viewpoint, there is no *guaranteed* role for rationality within naturalism. In the end, one might be left with no more than the kernel of instrumental rationality.

The Kochen-Specker Theorem

The Kochen-Specker theorem is an important, but subtle, topic in the foundations of quantum mechanics (QM). The theorem provides a powerful argument against the possibility of interpreting QM in terms of hidden variables (HV). We here present the theorem/argument and the foundational discussion surrounding it at different levels. The reader looking for a quick overview should read the following sections and subsections: 1, 2, 3.1, 3.2, 4, and 6. Those who read the whole entry will find proofs of some non-trivial claims in supplementary documents.

§1: Introduction

QM has the peculiar property that quantum-mechanical states imply, in general, only statistical restrictions on the results of measurements. The natural conclusion to be drawn is that these states are incomplete descriptions of quantum systems. QM, thus, would be incomplete in the sense that a typical

QM state description of an individual system could be supplemented with a more complete description in terms of an HV theory. In an HV description of the system the QM probabilities would be naturally interpreted as epistemic probabilities of the sort that arise in ordinary statistical mechanics. Such an HV description might not be practically useful, but one is tempted to think that it should at least be possible in principle. There are, however, two powerful theorems to the effect that such description is impossible even in principle: QM, given certain extremely plausible premises, cannot be supplemented by an HV theory. The more famous of these two theorems is Bell's theorem which states that, given a premise of locality, an HV model cannot match the statistical predictions of QM. The second important no-go theorem against HV theories is the theorem of Kochen and Specker (KS) which states that, given a premise of noncontextuality (to be explained presently) certain sets of QM observables cannot consistently be assigned values at all (even before the question of their statistical distributions arises).

Before seeing the workings of the KS theorem in some detail, we must clarify why it is of importance to philosophers of science. The explicit premise of HV interpretations is one of *value definiteness*:

> (VD) All observables defined for a QM system have definite values at all times.

VD, however, is motivated by a more basic principle, an apparently innocuous realism about physical measurement which, initially, seems an indispensable tenet of natural science. This realism consists in the assumption that whatever exists in the physical world is causally independent of our measurements which serve to give us information about it. Now, since measurements of all QM observables, typically, yield more or less precise values, there is good reason to think that such values exist independently of any measurements - which leads us to assume VD. (Note that we do not need to assume here that the values are faithfully revealed by measurement, but only that they exist!) We can concretize our innocuous realism in a second assumption of *noncontextuality*:

> (NC) If a QM system possesses a property (value of an observable), then it does so independently of any measurement context, i.e. independently of *how* that value is eventually measured.

This means that if a system possesses a given property, it does so independently of possessing other values pertaining to other arrangements. So, both our assumptions incorporate the basic idea of an independence of physical reality from its being measured.

The KS theorem establishes a contradiction between VD + NC and QM; thus, acceptance of QM logically forces us to renounce either VD or NC. However, the situation is more dramatic than it would initially seem. VD is the key motivating assumption of the HV programme in the sense that, if feasible, it would most naturally explain the statistical character of QM and most elegantly explain away the infamous measurement problem haunting all interpreters of QM [see the entries on quantum mechanics and measurement in quantum theory for details]. But, as we just saw, the second assumption NC is motivated by the same innocuous realism which embodies a standard of scientific rationality, and it is far from obvious what an interpretation obeying this standard only partly, i.e. endorsing only VD but rejecting NC,

should look like. This complex of issues -- namely, (1) VD + NC contradict QM; (2) the conceptual difficulties of interpreting QM provide a strong motivation for VD; (3) it is not obvious how to come up with a plausible story about QM containing VD, but not NC -- is what fuels philosophical interest in the KS theorem.

§2: Background to the KS Theorem

In the following, we will presuppose some familiarity with elementary QM notions like 'state', 'observable', 'value' and their mathematical representatives 'vector', '(self-adjoint) operator' and 'eigenvalue' [see the entry on quantum mechanics for details]. We will usually identify observables and the operators on an appropriate Hilbert space which represent them; if there is a need to distinguish operators and observables, we write the operators underlined and in boldface. (Thus an operator $\underline{\mathbf{A}}$ represents an observable A.)

The present section states some elements of the historical and systematic background of the KS theorem. Most importantly, an argument by von Neumann (1932), a theorem by Gleason (1957), and a critical discussion of both plus a later argument by Bell (1966) have to be considered. Von Neumann, in his famous 1932 book *Die mathematischen Grundlagen der Quantenmechanik*, disputed the possibility of providing QM with an HV underpinning. He gave an argument which boils down to the following: Consider the mathematical fact that, if $\underline{\mathbf{A}}$ and $\underline{\mathbf{B}}$ are self-adjoint operators, then any linear combination of them (any $\underline{\mathbf{C}} = \alpha\underline{\mathbf{A}} + \beta\underline{\mathbf{B}}$, where α, β are arbitrary real numbers) is also a self-adjoint operator. QM further dictates that for any QM state:

> (1) If A and B (represented by self-adjoint operators $\underline{\mathbf{A}}$ and $\underline{\mathbf{B}}$) are observables on a system, then there also is an observable C (represented by self-adjoint operator $\underline{\mathbf{C}}$ defined as before) on the same system.
>
> (2) If the expectation values of A and B are given by $\langle A \rangle$ and $\langle B \rangle$, then C's expectation value is given by $\langle C \rangle = \alpha\langle A \rangle + \beta\langle B \rangle$.

Now consider A, B, C, as above, and let their values be *v*(A), *v*(B), *v*(C). Consider a 'hidden state' V which determines *v*(A), *v*(B), *v*(C). We can then derive from V trivial 'expectation values' which are just the possessed values themselves: $\langle A \rangle_V = v(A)$, and so on.[1] Of course, these 'expectation values' do not, in general, equal the QM ones: $\langle A \rangle_V \neq \langle A \rangle$ (we would indeed think of the latter as averages over the former for different hidden states V!), but we require that the $\langle A \rangle_V$, like the $\langle A \rangle$, conform to (2). This automatically entails that the values themselves must conform to a condition parallel to (2), i.e.:

> (3) $v(C) = \alpha v(A) + \beta v(B)$.

This, however, is impossible, in general. An example very easily shows how (3) is violated, but because of its simplicity it also shows the argument's inadequacy. (This example is not due to von Neumann himself, but to Bell![2]) Let A = σx and B = σy, then operator C = $(\sigma x + \sigma y)/\sqrt{2}$ corresponds to the observable of the spin component along the direction bisecting *x* and *y*. Now all spin components have (in suitable units) possible values ±1 only, thus, the HV proponent is forced to ascribe ±1 to A, B, C as values, and thus as ‘expectation values’. This, in turn, implies (3) which obviously cannot be fulfilled, since $\pm 1 \neq (\pm 1 + \pm 1)/\sqrt{2}$.

The example illustrates why von Neumann's argument is unsatisfying. Nobody disputes the move from (2) to (3) for compatible observables, i.e. those which, according to QM, are jointly measurable in one arrangement. The above choice of A, B, C, however, is such that any two of them are incompatible, i.e. are not jointly observable. For these we will not want to require any HV interpretation to meet (3), but only (2). The hidden values need not conform with (3) in general, only the averages of their values in a series of tests must conform with (2). The authority of von Neumann's argument comes from the fact that requirements (1) and (2), *for QM states*, are consequences of the QM formalism, but this does not in itself justify extending these requirements to the hypothetical *hidden states*. Indeed, if (3) were unrestrictedly true, this would nicely explain, in the presence of hidden values, why (2) is. Von Neumann apparently thought that the HV proponent is committed to this explanation, but this seems an implausible restriction.

The KS theorem remedies this defect, spotted by Bell in von Neumann's argument, and thus strengthens the case against HV theories insofar as KS assume (3) only for sets of observables {A, B, C} which are all mutually compatible. The theorem requires that only for compatible observables assumption (3) must hold, which is something the HV theorist cannot reasonably deny.

A second, independent line of thought leading to the KS theorem is provided by Gleason's theorem (Gleason 1957). The theorem states that on a Hilbert space of dimension greater than or equal to 3, the only possible probability measures are the measures $\mu(P_\alpha) = Tr(P_\alpha W)$, where P_α is a projection operator, W is the statistical operator characterizing the system's actual state and Tr is the trace operation. The P_α can be understood as representing yes-no observables, i.e. questions concerning whether a QM system represented by a Hilbert space of dimension greater than or equal to 3 has a property α or not, and every possible property α is associated uniquely with a vector $|\alpha\rangle$ in the Hilbert space -- so, the task is to unambiguously assign probabilities to all vectors in the space. Now, the QM measure μ is continuous, so Gleason's theorem in effect proves *that every probability assignment to all the possible properties in a three-dimensional Hilbert space must be continuous*, i.e. must map all vectors in the space continuously into the interval [0, 1]. On the other hand, an HV theory (if characterized by VD + NC) would imply that of every property we can say whether the system has it or not. This yields a trivial probability function which maps all the P_i to either 1 or 0, and, provided that values 1 and 0 both occur (which follows trivially from interpreting the numbers as probabilities), this function must clearly be discontinuous (cf. Redhead 1987: 28).

This is the easiest argument against the possibility of an HV interpretation afforded by Gleason's theorem. Bell (1966: 6-8) offers a variant with a particular twist which later is repeated as the crucial step in the KS

theorem. (This explains why some authors (like Mermin 1990b) call the KS theorem the *Bell*-Kochen-Specker theorem; they think that the decisive idea of the KS theorem is due to Bell.[3]) He proves that the mapping μ dictates that two vectors $|\alpha\rangle$ and $|\alpha'\rangle$ mapped into 1 and 0 cannot be arbitrarily close, but must have a minimal angular separation, while the HV mapping, on the other hand, requires that they must be arbitrarily close.

After having offered his variant of the argument against HV theories from Gleason's theorem, Bell proceeds again to criticise it. The strategy parallels the one directed against von Neumann. Bell points out that his own Gleason-type argument against arbitrary closeness of two opposite-valued points presupposes non-trivial relations between values of non-commuting observables, which are only justified, given an assumption of noncontextuality (NC). He proposes as an analysis of what went wrong that his own argument "tacitly assumed that measurement of an observable must yield the same value independently of what other measurements may be made simultaneously" (1966: 9). In opposition to von Neumann, the Gleason-type argument derives restrictions on value assignments like (3) only for sets of compatible observables; but still one and the same observable can be a member of different commuting sets, and it is essential to the arguments that the observable gets assigned the same value in both sets, i.e. that the value assignment is not sensitive to a measurement context.

The KS theorem improves on the argument from Gleason's theorem. First, the authors repeat, in effect, Bell's proof that two vectors in the Hilbert space having values 1 and 0 cannot be arbitrarily close. However, while the Gleason argument and Bell's variant assume value assignments for a continuum of vectors in the Hilbert space, KS are able to explicitly present a discrete, even finite set of observables in the space for which an HV value assignment would lead to inconsistency. Obviously, the assumptions needed for the step of establishing that two opposite-valued points cannot be arbitrarily close are still in play in KS's improvement -- especially NC is! -- so Bell's criticism of his own Gleason-type argument survives that improvement.

Despite Bell's reasoning, the KS argument is of crucial importance in the HV discussions for two reasons: (1) It involves only a finite set of discrete observables. It thus avoids a possible objection to Bell's Gleason-type argument, namely that "it is not meaningful to assume that there are a continuum number of quantum mechanical propositions [viz. experiments]" (Kochen and Specker 1967: 70/307). So the KS theorem closes a loophole which a HV proponent might spot in Bell's argument. (2) KS propose a one-particle system as a physical realization of their argument. Thus, the argument trivially involves no separability or locality assumptions. Indeed, Bell first pointed out the tacit noncontextuality premise, but did so only in passing, and then, in the final section discussed an example of a two-particle system. Here, an eventual contextuality returns as nonseparability of the two particles, but Bell does not state the connection explicitly. Nor does he point out that the issue about the possibility of HV interpretations is, at bottom, not one about (non)separability or (non)locality, but rather one about (non)contextuality.[4] (After all, Bell's own argument against HV interpretations involves separability and/or locality assumptions!) This fact, however, is clearly illustrated by KS-type arguments.

§3: Statement and Proof of the KS Theorem

§3.1: Statement of the KS Theorem

An explicit statement of the KS theorem runs thus:

> Let H be a Hilbert space of QM state vectors of dimension $x \geq 3$. Let M be a set containing *y* observables, defined by operators on H. Then, for specific values of *x* and *y*, the following two assumptions are contradictory:
>
> (KS1) All *y* members of M simultaneously have values, i.e. are unambiguously mapped onto real unique numbers (designated, for observables A, B, C, ... by *v*(A), *v*(B), *v*(C), ...).
>
> (KS2) Values of observables conform to the following constraints:
>
> > (a) If A, B, C are all compatible and C = A+B, then *v*(C) = *v*(A)+*v*(B);
> >
> > (b) if A, B, C are all compatible and C = A·B, then *v*(C) = *v*(A)·*v*(B).

Assumption KS1 of the theorem obviously is an equivalent of VD. Assumptions KS2 (a) and (b) are called the *Sum Rule* and the *Product Rule*, respectively, in the literature. (The reader should again note that, in opposition to von Neumann's implicit premise, these rules non-trivially relate the values of *compatible* observables only.) Both are consequences of a deeper principle called the functional composition principle (FUNC), which in turn is a consequence of (among other assumptions) NC. The connection between NC, FUNC, Sum Rule and Product Rule will be made explicit in §4.

In the original KS proof *x*=3 and *y*=117. More recently proofs involving less observables have been given by (among many others) Peres (1991, 1995) for *x*=3 and *y*=33 and by Kernaghan (1994) for *x*=4 and *y*=20. The KS proof is notoriously complex, and we will only sketch it in §3.4. The Peres proof establishes the KS result in full strength, with great simplicity, and, moreover, in an intuitively accessible way, since it operates in three dimensions; we refer the reader to Peres (1995: 197-99). The Kernaghan proof establishes a contradiction in four dimensions. This is a weaker result, of course, than the KS theorem (since every contradiction in 3 dimensions is also a contradiction in higher dimensions, but not conversely). However, the proof is so much simpler that we present it for starters in §3.2. Finally, in §3.5, we explain an argument by Clifton (1993) where *x*=3 and *y*=8 and an additional statistical assumption yields an easy and instructive KS argument.

Return to Table of Contents

§3.2: A Quick KS Argument in Four Dimensions

A particularly easy KS argument proceeds on a four-dimensional Hilbert space H4. In order to get the gist of it quickly, the reader has to accept the following two facts on faith:

(1) From KS2 we can derive a constraint on value assignments to projection operators, namely that for every set of projection operators P_1, P_2, P_3, P_4, corresponding to the four distinct eigenvalues q_1, q_2, q_3, q_4 of an observable Q on H4 the following holds:

$$(\mathrm{VC1}') \quad v(P_1) + v(P_2) + v(P_3) + v(P_4) = 1, \text{ where } v(P_i) = 1 \text{ or } 0, \text{ for } i = 1, 2, 3, 4.$$

((VC1′) is a variant of (VC1) which we prove explicitly in the next section.) This means in effect that of every set of four orthogonal rays in H4 exactly one is assigned the number 1, the others 0.

(2) Although the Hilbert space mentioned in the theorem, in order to be suited for QM, must be *complex*, it is enough, in order to show the inconsistency of claims KS1 and KS2, to consider a *real* Hilbert space of the same dimension. So, instead of H4 we consider a real Hilbert space R4 and translate VC1′ into the requirement: Within every set of orthogonal rays in R4, exactly one is assigned the number 1 and the others 0. As usual in the literature, we translate all this into the following colouring problem: *Within every set of orthogonal rays in R4, exactly one must be coloured white and the others black.* This, however, is impossible, as is shown immediately by the following table (Kernaghan 1994):

1,0,0,0	1,0,0,0	1,0,0,0	1,0,0,0	-1,1,1,1	-1,1,1,1	1,-1,1,1	1,1,-1,1	0,1,-1,0	0,0,1,-1	1,0,1,0
0,1,0,0	0,1,0,0	0,0,1,0	0,0,0,1	1,-1,1,1	1,1,-1,1	1,1,-1,1	1,1,1,-1	1,0,0,-1	1,-1,0,0	0,1,0,1
0,0,1,0	0,0,1,1	0,1,0,1	0,1,1,0	1,1,-1,1	1,0,1,0	0,1,1,0	0,0,1,1	1,1,1,1	1,1,1,1	1,1,-1,-1
0,0,0,1	0,0,1,-1	0,1,0,-1	0,1,-1,0	1,1,1,-1	0,1,0,-1	1,0,0,-1	1,-1,0,0	1,-1,-1,1	1,1,-1,-1	1,-1,-1,1

There are 4 x 11 = 44 entries in this table. These entries are taken from a set of 20 rays (so we allow for repeats). [Recall that to specify a ray or line through the origin in four dimensions, it suffices to give the four coordinates of any single point (apart from the origin) that the line contains. For example, "1,0,0,0" denotes the unique line containing the points with coordinates "0,0,0,0" and "1,0,0,0", which line is, of course, just the "x-axis".] It is easy to verify that every column in the table represents a set of four *orthogonal* rays (simply calculate the dot products between the vectors within each column --- they are always zero). Since the number of columns is 11, we must end up with an *odd* number of the table's entries coloured white. On the other hand, it can be checked that each of the 20 rays appears either twice or four times in the table. So any time we designate a particular one of those rays as white, we commit ourselves to colouring an even number of the entries white. It follows that the total number of table entries coloured white must be even, *not* odd. Thus, a colouring of the 20 ray set in accordance with VC1′ is impossible. (Note for future reference that the first part of the argument -- the argument for ‘odd’ -- uses only VC1′, while the second -- the argument for ‘even’ -- relies essentially on NC, by assuming that occurrences of the same ray in different columns get assigned the same number!)

Return to Table of Contents

§3.3: The Original KS Argument. Technical Preliminaries.

The original KS proof operates on a three-dimensional complex Hilbert space H3. It requires two things: (1) sets of triples of rays which are orthogonal in H3; (2) a constraint to the effect that of every orthogonal triple one ray gets assigned the number 1, the two others 0. Both things are achieved thus:

We consider an arbitrary operator Q on H3 with three distinct eigenvalues q_1, q_2, q_3, its eigenvectors $|q_1>$, $|q_2>$, $|q_3>$, and projection operators P_1, P_2, P_3 projecting on the rays spanned by these vectors. Now, P_1, P_2, P_3 are themselves observables (namely, P_i is a 'yes-no observable' corresponding to the question 'Does the system have value q_i for Q?'). Moreover, P_1, P_2, P_3 are mutually compatible, so we can apply the Sum Rule and Product Rule, and thereby derive a constraint on the assignment of values (Proof):

(VC1) $v(P_1) + v(P_2) + v(P_3) = 1$, where $v(P_i) = 1$ or 0, for i = 1, 2, 3.

The arbitrary choice of an observable Q defines new observables P_1, P_2, P_3 which, in turn, select rays in H3. So, to impose that observables P_1, P_2, P_3 all have values means to assign numbers to rays in H3, and VC1, in particular, means that of an arbitrary triple of orthogonal rays, specified by choice of an arbitrary Q (briefly: an orthogonal triple in H3), exactly one of its rays is assigned 1, the others 0. Now, if we introduce different incompatible observables Q, Q', Q'', ... these observables select different orthogonal triples in H3. Assumption (1) of the KS theorem (which, effectively, is VD) now tells us that every one of these triples has three values, and VC1 tells us that these values must be for every triple, exactly {1, 0, 0}. What KS now shows is that, *for a specific set of orthogonal triples in H3, an assignment of numbers* {1, 0, 0} *to every one of them is impossible*. Further reflection yields that while H3 is complex, it is in fact enough to consider a real three-dimensional Hilbert space R3. For, we can show that if an assignment of values according to VC1 is possible on H3, then it is possible on R3. Contrapositively, if the assignment is impossible on R3, then it is impossible on H3. So we can fulfill the conditions necessary to get the KS proof started and at the same time reduce the problem to one on R3. Now, the equivalent in R3, of an arbitrary orthogonal triple in H3, is, again, an arbitrary triple of orthogonal rays (briefly: an orthogonal triple in R3). So, if KS want to show that, for a specific set of n orthogonal triples in H3 (where n is a natural number), an assignment of numbers {1, 0, 0} to every one of them is impossible, it is enough for them to show that, *for a specific set of n orthogonal triples in R3, an assignment of numbers* {1, 0, 0} *to every one of them is impossible*. And this is exactly what they do.

It should be stressed, however, that at this point there is no direct connection between R3 and physical space. KS wish to show that for an arbitrary QM system requiring a representation in a Hilbert space of at least three dimensions, the ascription of values in conjunction with condition (KS2) (Sum Rule and Product Rule) is impossible, and in order to do this it is sufficient to consider the space R3. This space R3, however, does not represent physical space for the quantum system at issue. In particular, orthogonality in R3 is not to be confused with orthogonality in physical space. This becomes obvious, if we move to an

example of a QM system sitting in physical space and at the same time requiring a QM representation in H3, e.g. a one particle spin-1 system measured for spin. Given one arbitrary direction α in physical space and an operator $S\alpha$ representing the observable of a spin component in direction α, H3 is spanned by the eigenvectors of $S\alpha$, namely $|S\alpha=1>$, $|S\alpha=0>$, $|S\alpha=-1>$, which are mutually orthogonal in H3. The fact that these three vectors corresponding to three possible results of measurement in one spatial direction are mutually orthogonal illustrates the different senses of orthogonality in H3 and in physical space. (The reason lies, of course, in the structure of QM which represents different values of an observable by different directions in H3.) Now, if orthogonality in H3 differs from orthogonality in physical space, and we just use R3 to prove a result about H3, then certainly orthogonality in R3 bears no direct connection with physical space.

KS themselves, in the abstract, proceed in exactly the same way, but they illustrate with an example that *does* establish a direct connection with physical space. It is important to see this connection, but also to be clear that it is produced by KS's example and is not inherent in their mathematical result. KS propose to consider a one-particle spin 1 system and the measurement of the squared components of orthogonal directions of spin in physical space S_x^2, S_y^2, S_z^2 which are compatible (while S_x, S_y, S_z themselves are not).[5] Measurement of a squared component of spin determines its absolute magnitude, but not its direction. Here, we derive a slightly different constraint on value assignments, again using the Sum Rule and the Product Rule (Proof):

(VC2) $v(S_x^2) + v(S_y^2) + v(S_z^2) = 2$, where $v(S\alpha^2) = 1$ or 0, for $\alpha = x, y, z$.

Now, since S_x^2, S_y^2, S_z^2 are compatible, there is an observable O such that S_x^2, S_y^2, S_z^2 are all functions of O. So, the choice of an arbitrary O fixes S_x^2, S_y^2, S_z^2 and, since these latter can be directly associated with mutually orthogonal rays in H3, again fixes the choice of an orthogonal triple in H3. The resulting problem here is to assign numbers {1, 1, 0} to an orthogonal triple in H3 specified by the choice of O or, more directly, S_x^2, S_y^2, S_z^2. This is, of course, the mirror-image of our previous problem of assigning numbers {1, 0, 0} to such a triple, and we need not consider it separately.

However, the choice of a specific O which selects observables S_x^2, S_y^2, S_z^2 at the same time selects three orthogonal rays in physical space, namely by fixing a coordinate system $\pm x$, $\pm y$, $\pm z$ (which defines along which orthogonal rays the squared spin components are to be measured) *in physical space*. So now, by choice of an observable O, there *is* a direct connection of with directions in H3: orthogonality in H3 now *does* correspond to orthogonality in physical space. The same holds for R3, if, in order to give an argument for H3, we consider R3. Orthogonality in R3 now corresponds to orthogonality in physical space. It is important to notice that this correspondence is not necessary to give the argument, even if we insist that the pure mathematical facts should be supplemented by a physical interpretation - since we have, just before, seen an example without any correspondence. The point is only that we *can* devise an example such that there is a correspondence. In particular, we can now follow the proof in R3 and all along imagine a system sitting in physical space, namely a spin 1 particle, returning three values upon measurement of three physical magnitudes, associated directly with orthogonal directions in physical

space, namely $v(S_x^2)$, $v(S_y^2)$, $v(S_z^2)$, for arbitrary choices of *x*, *y*, *z*. The KS proof then shows that it is impossible (given its premises, of course) to assign to the spin 1 particle values for all these arbitrary choices. That is, the KS argument shows that (given the premises) a spin 1 particle cannot possess all the properties at once which it displays in different measurement arrangements.

Three further features which have become customary in KS arguments need to be mentioned:

(1) Obviously, we can unambiguously specify any ray in R3 through the origin by just giving one point contained in it. KS thus identify rays with points on the unit sphere E. KS do not need to refer to concrete coordinates of a certain point, since their argument is ‘coordinate-free’. We will, however, for illustration sometimes mention concrete points and then (a) use Cartesian coordinates to check orthogonality relations and (b) specify rays by points not lying on E. (Thus, e.g., the triple of points (0, 0, 1), (4, 1, 0), (1, -4, 0) is used to specify a triple of orthogonal rays.) Both usages conform with the recent literature (see e.g. Peres (1991) and Clifton (1993)).

(2) We translate the constraints (VC1) and (VC2) on value ascriptions into constraints for colouring the points. We can, operating under (VC1) colour the points white (for "1") and black (for "0"), or, operating under (VC2) colour the points white (for "0") and black (for "1"). In either case the constraints translate into the same colouring problem.

(3) KS illustrate orthogonality relations of rays by graphs which have come to be called *KS diagrams*. In such a diagram each ray (or point specifying a ray) is represented by a vertex. Vertices joined by a straight line represent orthogonal rays. The colouring problem then translates into the problem of colouring the vertices of the diagram white or black such that joined vertices cannot be both white and triangles have exactly one white vertex.

Return to Table of Contents

§3.4: The Original KS Argument. Sketch of the Proof.

KS proceed in two steps.

(1) In the first (and decisive) step they show *that two rays with opposite colours cannot be arbitrarily close*. They show that the diagram Γ_1 depicted in Fig. 1 which consists of ten vertices including a_0 and a_9 is constructible, if a_0 and a_9 are separated by an angle θ with $0 \leq \theta \leq \sin^{-1}(1/3)$ (Proof).

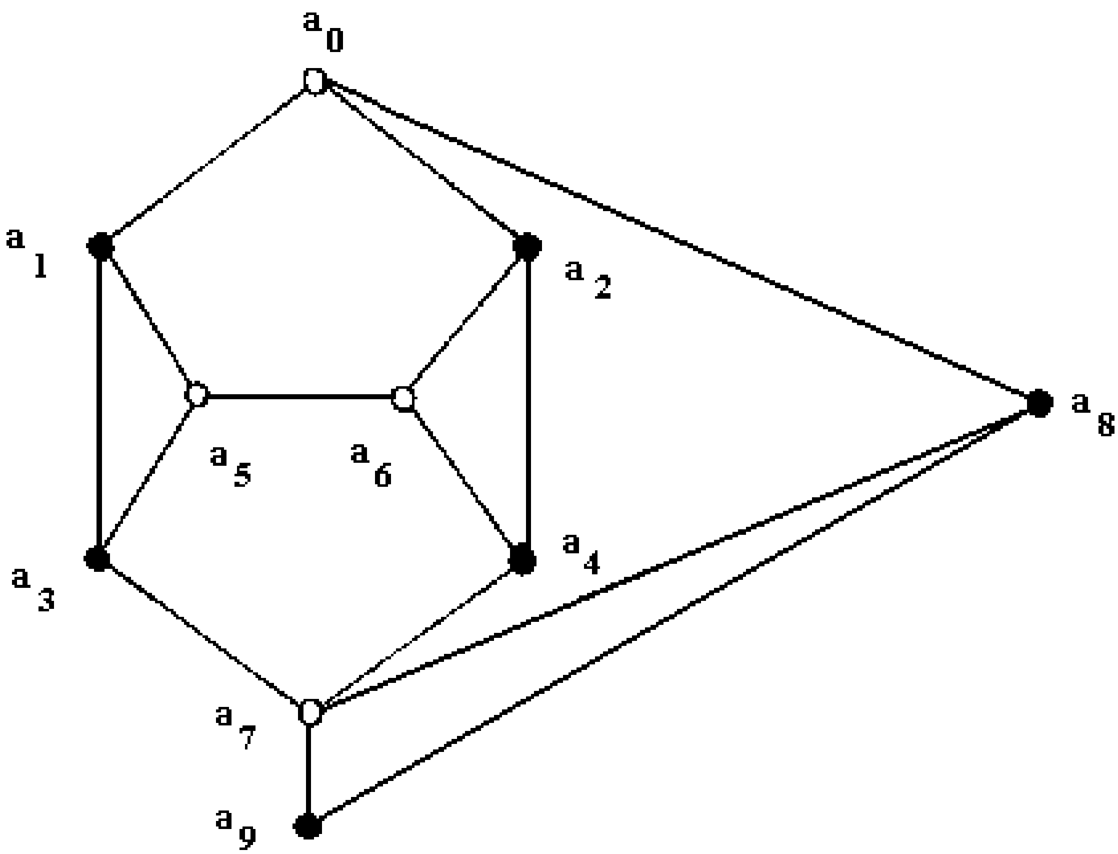

Figure 1: Ten-point KS graph Γ_1 with inconsistent colouring.

What this step shows is the following: It is possible to construct this KS diagram, i.e. to specify ten rays in R3 with orthogonality relations as specified in the diagram, but only if rays a_0 and a_9 are closer than $\sin^{-1}(1/3)$. Consider now (for a *reductio ad absurdum*) that a_0 and a_9 have different colours. We arbitrarily colour a_0 white and a_9 black. The colouring constraints then force us to colour the rest of the diagram as is done in fig.1, but this forces that a_5 and a_6 are orthogonal and both white -- which is forbidden. Hence, two points closer than $\sin^{-1}(1/3)$ cannot have different colour. Contrapositively, two points of different colour cannot be closer than $\sin^{-1}(1/3)$.

(2) KS now construct another quite complicated KS diagram Γ_2 in the following way. They consider a realization of Γ_1 for an angle θ=18° < $\sin^{-1}(1/3)$. Now they choose three orthogonal points p_0, q_0, r_0 and space interlocking copies of Γ_1 between them such that every instance of point a_9 of one copy of Γ_1 is identified with the instance of a_0 of the next copy. In this way five interlocking copies of Γ_1 are spaced between p_0 and q_0 and all five instances of a_8 are identified with r_0 (likewise for q_0, r_0, and p_0, and for r_0, p_0, and q_0). That Γ_2 is constructible is borne out directly by the construction itself. Spacing out five copies of with angles θ=18° between instances of a_0 will space out an angle of 5x18° = 90° which is exactly what is required. Moreover, wandering from one copy of Γ_1 to the next between, say, p_0 and q_0 is equivalent to a rotation of the copy about the axis through the origin and r_0 of 18° which evidently

conserves the orthogonality between the points a_0 and a_9 of the copy and r_0.

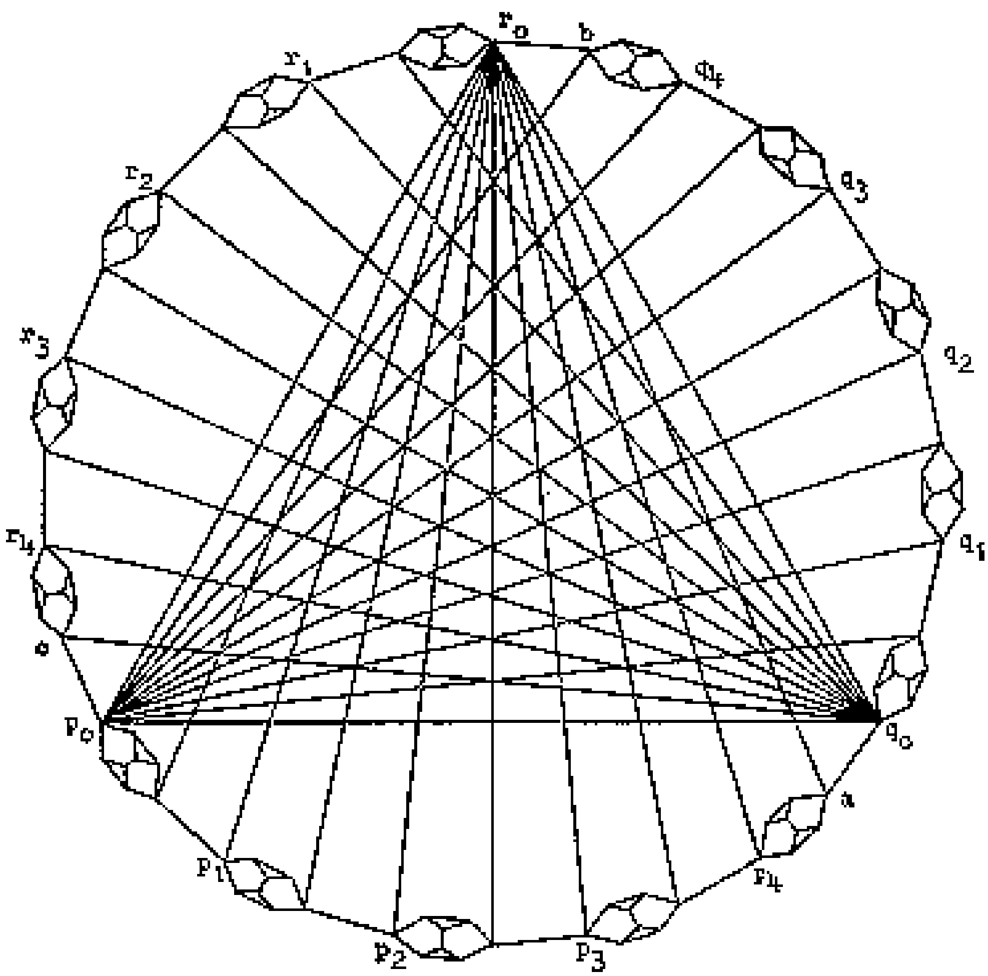

Figure 2: 117-point KS graph Γ_2
(*From* Kochen and Specker 1967, 69; *by permission of the Indiana University Mathematics Journal*)

However, although Γ_2 is constructible it is *not* consistently colourable. From the first step we know that a copy of Γ_1 with ϑ=18° forces that points a_0 and a_9 have equal colour. Now, since a_9 in one copy of Γ_1 is identical to a_0 in the next copy, a_9 in the second copy must have the same colour as a_0 in the first. Indeed, by repetition of this argument all instances of a_0 must have the same colour. Now, p_0, q_0, r_0 are identified with points a_0, so they must be either all white or all black - both of which are inconsistent with the colouring constraint that exactly one of them be white.

If from the 15 copies of Γ_1 used in the process of constructing Γ_2 we subtract those points that were identified with each other, we end up with 117 different points. So what KS have shown is that a set of 117 observables cannot consistently be assigned values in accordance with VC1 (or, equivalently, VC2).

Note that in the construction of Γ_1, i.e. the set of 10 points forming 22 interlocking triples, all points

except a_9 appear in more than one triple. In Γ_2 every point appears in a multiplicity of triples. It is here that the noncontextuality premise is crucial to the argument: We assume that an arbitrary point keeps its value 1 or 0 as we move from one orthogonal triple to the next (i.e. from one maximal set of compatible observables to another).

§3.5: A Statistical KS Argument in Three Dimensions (Clifton)

Finally, we return to R3. Recall KS's first step which establishes that two points with opposite colour cannot be arbitrarily close. It is this first step which carries the whole force of the argument. Bell had established it in a different way and had then argued that in a noncontextual HV interpretation points with opposite colour must be arbitrarily close. It is this first step which Clifton exploits in an argument that combines Bell's and KS's ideas.

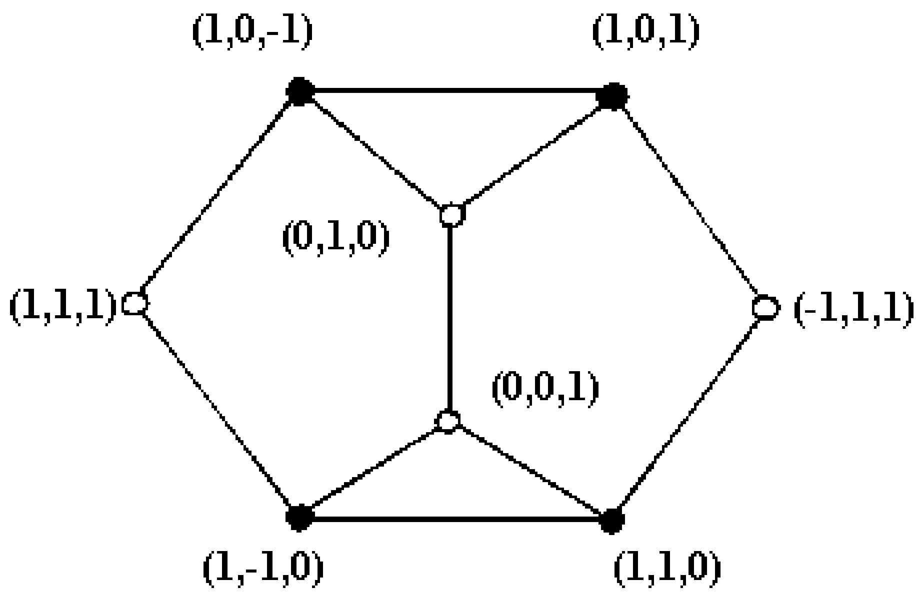

Figure 3: 8-point KS-Clifton graph Γ_3 with inconsistent colouring.

Consider the KS diagram Γ_3 shown in Figure 3 which obviously is a part of KS's Γ_1, but which has additional concrete assignments of eight points satisfying the orthogonality relations (and thus proving directly that Γ_3 is constructible). From our previous colouring constraints (joined points are not both white and a triangle has exactly one white point) we see immediately that Γ_3 is colourable only if the outermost points are not both white (which would force, as shown in fig. 3, that two joined points are white - contrary to the constraints). Moreover, we easily calculate the angle between the two outermost points to be $\cos^{-1}(1/3)$.[6] So we conclude that if one wants to colour all eight points and wants to colour white one of the outer ones, then the other must be black. Taking into account that we can insert a

diagram between any two points in R3 which are separated by exactly the angle $\cos^{-1}(1/3)$ and translating our problem back from a colouring problem into KS's example (constraint VC2), we end with a constraint VC2′:

> (VC2′) If, for a spin-1 system, a certain direction *x* of spin in space is assigned value 0, then any other direction *x*′ which lies away from *x* by an angle $\cos^{-1}(1/3)$ must be assigned value 1, or, in symbols: If $v(S_x)=0$, then $v(S_{x'})=1$.

The argument so far has made use of the original KS conditions KS1 and KS2. We now assume, in addition, that any constraint on value assignments will show up in the measurement statistics. In particular: A value assignment dictated by a constraint entails that this assigned value with certainty is the result of any measurement respecting the constraint. Or in symbols:

> (3) If prob[v(A)=a] = 1, and v(A)=a implies v(B)=b, then prob[v(B)=b] = 1.

Despite the use of statistics, this reasoning crucially differs from von Neumann's argument. Von Neumann had argued that algebraic relations between values should transfer into the statistics of the measured values, therefore the QM constraints on these statistics should have value constraints as their exact mirror images - which reasoning leads us to derive value constraints from statistical constraints (for arbitrary observables). Here, on the contrary, we derive a value constraint independently from any statistical reasoning, and then conclude that this constraint should transfer into the measurement statistics.[7]

Now, VC2′ and the statistical condition (3) entail: If prob[$v(S_x)=0$]=1, then prob[$v(S_{x'})=1$]=1. This, however, contradicts the statistics derived from QM for a state where prob[$v(S_x)=0$] = 1.[8] In fact, there is a probability of 1/17 that $v(S_{x'}=0)$. So, in a long-run test 1/17 of the spin-1 particles will violate the constraint.

1/17 may not seem a terribly impressive number, but if we accept Clifton's statistical reasoning, we have an entirely valid KS argument establishing a contradiction between an HV interpretation of QM and the very predictions of QM. Moreover, Clifton presents a slightly more complex set of 13 observables yielding, along the same lines, a statistical contradiction of 1/3.

§4: The Functional Composition Principle

The key ingredients of the KS theorem are the constraints on value assignments spelled out in (2): the Sum Rule and Product Rule. They derive from a more general principle, called the *Functional Composition Principle* (FUNC).[9] The principle trades on the mathematical fact that for a self-adjoint

operator **A** operating on a Hilbert space, and an arbitrary function f: **R**→**R** (where **R** is the set of the real numbers), we can define f(**A**) and show that it also is a self-adjoint operator (hence, we write **f(A)**). If we further assume that to every self-adjoint operator there corresponds a QM observable, then the principle can be formulated thus:

> **FUNC:** Let **A** be a self-adjoint operator associated with observable A, let f: **R** → **R** be an arbitrary function, such that **f(A)** is another self-adjoint operator, and let $|\varphi\rangle$ be an arbitrary state; then **f(A)** is associated uniquely with an observable f(A) such that:
>
> $v(\mathrm{f(A)})^{|\varphi\rangle} = \mathrm{f}(v(\mathrm{A}))^{|\varphi\rangle}$

(We introduced the state superscript above to allow for a possible dependence of values on the particular quantum state the system is prepared in.) The Sum Rule and the Product Rule are straightforward consequences of FUNC (Proof). FUNC itself is not derivable from the formalism of QM, but a statistical version of it (called STAT FUNC) is [Proof]:

> **STAT FUNC:** Given A, f, $|\varphi\rangle$ as defined in FUNC, then, for an arbitrary real number *b*:
>
> $\mathrm{prob}[v(\mathrm{f(A)})^{|\varphi\rangle}=b] = \mathrm{prob}[\mathrm{f}(v(\mathrm{A}))^{|\varphi\rangle}=b]$

But STAT FUNC cannot only be derived from the QM formalism, it also follows from FUNC [Proof]. This can be seen as providing "a plausibility argument for FUNC" (Redhead 1987: 132): STAT FUNC is true, as a matter of the mathematics of QM. Now, if FUNC were true, we could derive STAT FUNC, and thus understand part of the QM mathematics as a consequence of FUNC.

But how can we derive FUNC itself, if not from STAT FUNC? It is a direct consequence of STAT FUNC and three assumptions (two of which are familiar from the introduction):

> **Value Realism (VR):** If there is an operationally defined real number α, associated with a self-adjoint operator **A** and distributed probabilistically according to the statistical algorithm of QM for **A**, i.e. if there exists a real number β with β=prob (v(**A**)=α), then there exists an observable A with value α.
>
> **Value Definiteness (VD):** All observables defined for a QM system have definite values at all times.
>
> **Noncontextuality (NC):** If a QM system possesses a property (value of an observable), then it does so independently of any measurement context.

Some comments on these conditions are in order. First, we need to explain the content of VR. The statistical algorithm of QM tells us how to calculate a probability from a given state, a given observable

and its value. Here we understand it as a mere mathematical device without any physical interpretation: Given a Hilbert space vector, an operator and its eigenvalues, the algorithm tells us how to calculate new numbers (which have the properties of probabilities). In addition, by ‘operationally defined’ we here simply mean ‘made up from a number which we know to denote a real property’. So, VR, in effect, says that, if we have a real property γ (value γ of an observable G), and we are able to construct from γ a new number α and find an operator **A** such that α is an eigenvalue of **A**, then (we have fulfilled everything necessary to apply the statistical algorithm; thus) **A** represents an observable A and its value α is a real property.

Secondly, concerning NC: A failure of NC could be understood in two ways. Either, the value of an observable might be context-dependent, although the observable itself is not; or, the value of an observable might be context-dependent, because the observable itself is. There are, however, good grounds to think that both options are equivalent. We will indeed assume that, if NC holds, this means that the *observable* -- and *thereby* also its value -- is independent of the measurement context, i.e. is independent of how it is measured. In particular, the independence from context of an observable implies that there is a 1:1 correspondence of observables and operators. This implication of NC is what we will use presently in the derivation of FUNC. *Conversely*, failure of NC will be construed solely as failure of the 1:1 correspondence.

From VR, VD, NC and STAT FUNC, we can derive FUNC as follows. Consider an arbitrary state of a system and an arbitrary observable Q. By VD, Q possesses a value $v(Q)=a$. Thus, we can form the number $f(v(Q))=b$ for an arbitrary function f. For this number, by STAT FUNC, prob[$f(v(Q))=b$] = prob[$v(f(Q))=b$]. Hence, we have, by transforming probabilities according to STAT FUNC, created a new self-adjoint operator **f(Q)**, and associated it with the two real numbers b and prob[$f(v(Q))=b$]. Thus, by VR, there is an observable corresponding to **f(Q)** with value b, hence $f(v(Q))=v(f(Q))$. By NC, that observable is unique, hence FUNC follows.

§5: Escaping the KS Argument

The previous section clarifies which possibilities the HV theorist has to escape the KS argument: denying one of the three premises which together entail FUNC (hence the Sum Rule and Product Rule).

§5.1: No General Value Definiteness

VD, we recall, was the fundamental presupposition of HV interpretations. So, if, in order to escape a powerful argument against the possibility of HV interpretations, these interpretations drop their fundamental motivation, this seems not to make much sense. But some interpreters point out that, between holding that only those observables which QM prescribes to have values[10] and holding that all of them have values, there is some leeway, namely, to propose that more observables, than prescribed in

QM, but not all, have values (‘partial value definiteness’). This option of partial value definiteness has been taken by various modal interpretations and also has been explored by John Bell in his ‘beable approach’ to QM (1987: ch.7).

The rocks and shoals of modal interpretations are beyond the scope of this article (see the entry on modal interpretations). We just note that it is by no means clear how these interpretations can manage to always pick out the right set of observables assumed to have values. ‘Right set’ here means that the observable actually measured must always be included (in order to avoid the measurement problem) and must always recover the QM statistics. We also mention two important results which cast doubt on the feasibility of modal interpretations: First, it can be shown that either partial value definiteness collapses into total value definiteness (i.e., VD) or classical reasoning about physical properties must be abandoned. (Clifton 1995). Second, it is possible to derive a kind of KS theorem even in certain modal interpretations (Bacciagaluppi 1995, Clifton 1996).

Return to Table of Contents

§5.2: Denial of Value Realism

The derivation of FUNC basically consists in the construction of an observable (i.e. f(Q)) via an operator (i.e. **f(Q)**) from the probability distribution of a number (i.e. f(*v*(Q)) which number in turn is constructed from another number, (i.e. *v*(Q)). Now, instead of denying that *v*(Q) exists in all cases (like the first option would have it), we can reject that the existence of a number α and the construction of **f(Q)** automatically lead to an observable, i.e. we reject VR. This amounts to rejecting that for every self-adjoint operator, there is a well-defined observable.

Now, in order to formulate VR we had to give a very reduced reading to the statistical algorithm, i.e. that it is a mere mathematical device for calculating numbers from vectors, operators and numbers. (What if we had done otherwise? Well, if we say: ‘Whatever fulfills the statistical algorithm is an observable’, we cannot very well suppose that an operator, in order to fulfill the algorithm, must be understood as an observable, since this would make the condition a trivial consequence of the algorithm.) This reading is very artificial and presupposes that a minimal interpretational apparatus required to make physical sense of some operators (like **Q**) can be withheld for others (like **f(Q)**).

Moreover, it seems entirely implausible to assume that some operators - sums and products of operators that are associated with well-defined observables - are themselves not associated with well-defined observables, even if they mathematically inherit exact values from their summands or factors. Put in a crude example, this would amount to saying that to ask for a system's energy is a well-defined question, while to ask for the square of the system's energy is not, even if, from our answer to the first question and trivial mathematics, we have a well-defined answer at hand. There seems no good a priori reason to justify this restriction. So, to make rejecting VR plausible at all, an additional proposal is made: It is crucial to the KS argument that one and the same operator is constructed from different maximal ones which are incompatible: **f(Q)** is identical to **g(P)**, where $\mathbf{PQ} - \mathbf{QP} \neq 0$. We now assume that only the

construction of **f(Q)** via Q, but not the one via P, leads to a well-defined observable.[11]

This move however, automatically makes some observables context-sensitive. So, this way of motivating the denial of VR amounts to a kind of contextualism, which we might come by cheaper, by directly rejecting NC, and without any tampering with the statistical algorithm. (This fact explains why we did not mention denial of VR as a separate option in the introduction.).

Return to Table of Contents

§5.3: Contextuality

Finally, we might accept VD and VR, but deny that our construction of an observable f(Q) is unambiguous. Thus, we accept that **f(Q)** and **g(P)** are mathematically identical, but physically they correspond to different observables, since an actual determination of *v*(f(Q)) must proceed via measuring Q, but the determination of *v*(g(P)) involves measuring P which is incompatible with Q. Since *v*(f(Q)) and *v*(g(P)) are outcomes of different measurement situations, there is no reason to assume that *v*(f(Q)) = *v*(g(P)). This way to block the KS proof comes to understanding f(Q) and g(P) as different observables (because of sensitivity to context), thus it amounts to rejecting NC. There are mainly two ways, in the literature, to further motivate this step. Accordingly, there are two important brands of contextuality to be discussed -- causal and ontological contextuality.

The KS argument has been presented for possessed values of a QM system - independently of considerations about measurement. Indeed, in the argument measurement was mentioned only once and in the negative - in NC. However, since now we consider the rejection of NC, we must also take into account measurement and its complications. An additional manifestation of our innocuous realism (see the introduction above) is a principle of *faithful measurement* (FM): QM measurement of an observable faithfully delivers the value which that observable had immediately prior to the measurement interaction. FM also is an extremely plausible presupposition of natural science. Moreover, FM entails VD (therefore we could have, using the stronger principle, given a KS argument for possible measurement results). Consider now the motivation, for the HV proponent, to reject NC. Obviously, the aim is to save other presuppositions, especially VD. Now, VD and NC are independent realist convictions, but NC and FM are not quite so independent. Indeed, we will see that rejection of NC entails the rejection of FM in one version of contextuality, and strongly suggests it in the other. (This makes more precise the somewhat cryptical remark from the introduction that it is not obvious what an interpretation endorsing the realist principle VD, but rejecting the realist principle NC, should look like. Such an interpretation would have to violate a third realist principle, i.e. FM.)

Causal Contextuality

An observable might be *causally* context-dependent in the sense that it is causally sensitive to how it is measured. The basic idea is that the observed value comes about as the effect of the system-apparatus interaction. Hence, measuring a system via interaction with a P-measuring apparatus might yield a value

v(g(P)), measuring the same system via interaction with a Q-measuring apparatus a different value v(f(Q)), although both observables are represented by the same operator **f(Q)** = **g(P)**. The difference in values is explained in terms of a context-dependence of the observables: The latter are context-dependent, since the different ways to physically realize them causally influence the system in different ways and thereby change the observed values.

If an interpreter wanted to defend causal contextuality, this would entail abandoning FM, at least for observables of the type f(Q) (non-maximal observables): Since their values causally depend on the presence of certain measurement arrangements, these arrangements are causally necessary for the values to come about, thus the values cannot be present before the system-apparatus interaction, and FM is violated. As an advantage of causal contextualism the following might be pointed out. It does not imply that the ontological status of the physical properties involved must change, i.e. does not imply that they become relational. If the property in an object is brought about via interaction with another one, it can still be one which the object has for itself after the interaction. However, the idea of causal contextuality is sometimes discussed critically, since there is reason to think that it may be empirically inadequate (see Shimony 1984, Stairs 1992).

Ontological Contextuality

An observable might be *ontologically* context-dependent in the sense that in order for it to be well-defined the specification of the observable it 'comes from' is necessary. Thus, in order to construct a well-defined observable from operator **f(Q)** = **g(P)**, we need to know whether it is physically realized via observable P or observable Q. This way out of the KS problem, was first proposed (but not advocated) by van Fraassen (1973). There are, then, as many observables and kinds of physical properties for an operator **f(Q)** as there are ways to construct **f(Q)** from maximal operators. Without further explanation, however, this idea just amounts to an ad hoc proliferation of physical magnitudes. A defender of ontological contextuality certainly owes us a more explicit story about the dependence of observable f(Q) on observable Q. Two possibilities come to mind:

(a) We might think that v(f(Q)) just is not a self-sustained physical property, but one which ontologically depends on the presence of another property v(Q). (Recall that in the proof of FUNC v(f(Q)) *is* constructed from v(Q).) But, since the position does not reject questions about values of f(Q) in a P-measurement situation as illegitimate (because it does not trade on a notion of an observable being well-defined in one context only!), this seems to lead to new and pressing questions, to say the least. As an attempt to defend a contextualist *hidden variables* interpretation, this position must concede that not only does the system have, in the Q-measurement situation, a value v(Q), but also, in a P-measurement situation, it has a value v'(Q), although perhaps $v'(Q) \neq v(Q)$. Now, questions for values of f(Q) in this situation at least are legitimate. Does v'(Q) install another $v'(f(Q)) \neq v(f(Q))$? Or does v'(Q), in opposition to v(Q), not lead to a value of f(Q), at all? Neither option seems plausible, for couldn't we, just by switching for a certain prepared system between a P- and Q-measurement situation either switch v(f(Q)) in and out of existence or switch between v(f(Q)) and v'(f(Q))? . (b) We might think that, in order for f(Q) to be well-defined, one measurement arrangement rather than the other is necessary. The idea is strongly reminiscent of Bohr's 1935 argument against EPR, and indeed may be viewed as the appropriate

extension of Bohr's views on QM to the modern HV discussion (see Held 1998, ch.7). In this version of ontological contextualism the property *v*(f(Q)), rather than depending on the presence of another property *v*(Q), is dependent on the presence of a Q-measuring apparatus. This amounts to a holistic position: For some properties it only makes sense to speak of them as pertaining to the system, if that system is part of a certain system-apparatus whole. Here, the question for values of f(Q) in a P-measurement situation *does* become illegitimate, since f(Q)'s being well-defined is tied to a Q-measurement situation. But again reservations apply. Does the position hold that, in opposition to f(Q), Q itself is well-defined in a P-measurement situation? If it does not, Q hardly can have a value (since not being well-defined was the reason to deny f(Q) a value) which means that we are not considering an HV interpretation any longer, and that there is no need to block the KS argument, at all. If it does, what explains that, in the P-measurement situation, Q remains well-defined, but f(Q) loses this status?

What becomes of FM in both versions of ontological contextualism? Well, if we remain agnostic about how the position could be made plausible, we can save FM, while, if we choose version (a) or (b) to make it plausible, we lose it. Consider first an agnostic denial of NC. FM said that every QM *observable* is faithfully measured. Now, contextualism splits an operator which can be constructed from two different noncommuting operators into two observables, and ontological contextualism does not try to give us a causal story which would ruin the causal independence of the measured value from the measurement interaction embodied in FM. We simply introduce a more fine-grained conception of observables, but for these new contextual observables still can impose FM.

However, the concrete versions of ontological contextualism, by attempting to motivate the contextual feature, ruin FM. Version (a) allows f(Q) to switch ‘on and off’ or to switch between different values upon the change between P- and Q-measurement situations - which is a flagrant violation of FM. Version (b) fares no better. It introduces the ontological dependence on the measuring arrangement. It is hard to see what else this should be, but the same causal dependence pushed to a higher, ‘ontological’ key. Again, couldn't we, just by flipping back and forth the measurement arrangement, change back and forth that f(Q) is well-defined, thus flip in and out of existence *v*(f(Q))?

Finally, we note that both types of ontological contextualism, in opposition to the causal version, *do* entail that system properties which we earlier thought to be intrinsic, become relational in the sense that a system can only have these properties either if it has certain others, or if it is related to a certain measurement arrangement.

§6: The Question of Empirical Testing

Famously, the violation of Bell's inequalities, prescribed by QM, has been confirmed experimentally. Is something similar possible for the KS theorem? We distinguish three questions: (1) Is it possible to realize the experiment proposed by KS as a motivation of their theorem? (2) Is it possible to test the principles leading to the theorem: the Sum Rule and Product Rule, FUNC, or NC? (3) Is it possible to test

the theorem itself?

(1) KS themselves describe a concrete experimental arrangement to measure S_x^2, S_y^2, S_z^2 on a one-particle spin 1 system as functions of one maximal observable. An orthohelium atom in the lowest triplet state is placed in a small electric field E of rhombic symmetry. The three observables in question then can be measured as functions of one single observable, the perturbation Hamiltonian H_s. H_s, by the geometry of E, has three distinct possible values measurement of which reveals which two observables of S_x^2, S_y^2, S_z^2 have value 1, which one has value 0 (see Kochen and Specker 1967: 72/311). This is, of course, a proposal to realize an experiment exemplifying our above value constraint (VC2). Could we also realize a (VC1) experiment, i.e. measure a set of commuting projectors projecting on eigenstates of one maximal observable? Peres (1995: 200) answers the question in the affirmative, discusses such an experiment, and refers to Swift and Wright (1980) for details about the technical feasibility. It seems, however, that, despite being possible in principle, no such experiment has been actually carried out (see Cabello and Garcìa-Alcaine (1998) for more discussion and another experimental proposal).

(2) In conjunction with manifestations of FUNC, i.e. the Sum Rule and the Product Rule, QM yields constraints like VC1 or VC2 that contradict VD. So providing concrete physical examples that could, given the Sum Rule and the Product Rule, instantiate VC1 or VC2, as just outlined, is not enough. We must ask whether these rules themselves can be empirically supported. There was considerable discussion in the early 80s about this question --- explicitly about whether the Sum Rule is empirically testable --- and there was general agreement that it is not.[12]

The reason is the following: Recall that the derivation of FUNC established uniqueness of the new observable f(Q) only in its final step (via NC). It is this uniqueness which guarantees that one operator represents exactly one observable such that observables (and thereby their values) in different contexts can be equated. This allows to establish indirect connections between different incompatible observables. Without this final step, FUNC must be viewed as holding relative to different contexts, the connection is broken and FUNC is restricted to one set of observables which are all mutually compatible. Then indeed FUNC, the Sum Rule and the Product Rule become trivial, and empirical testing in these cases would be a pointless question.[13] It is NC which does all the work and which deserves to be tested via checking whether for incompatible P, Q such that f(Q)=g(P) it is true that v(f(Q))=v(g(P)). Testing this, however, is impossible, due to the impossibility of simultaneously measuring P and Q.

(3) Very recently, it has been argued that the (physically reasonable) assumption of finitely precise measurement creates a decisive loophole in the KS argument (see Meyer 1999, Kent 1999, Clifton and Kent 1999; briefly MKC).[14] Indeed, if we consider a KS argument for measured values, infinite precision is crucial to the argument in two different ways: (1) It is necessary to the argument that the measured components of one triple (or quadruple) are exactly orthogonal. (2) It is necessary (to install NC) that two measurements intended to pick out the same observable as member of two different maximal sets, pick out exactly the same direction. If we relax this assumption of infinite precision, noncontextual HV models can be constructed. In these models, it is not exactly the sets of observables specified in the KS argument (or related arguments) by points in R3, but sets specified by points with

rational components (which approximate the former arbitrarily closely) that are colourable, i.e. that can consistently be assigned noncontextual values. So the argument ultimately trades on the fact that we cannot empirically distinguish between a ‘real point’ and its ‘rational’ approximation.

The MKC argument is hotly debated and the question whether it is relevant or even destructive to the KS argument is unsettled, so we shall just record part of the discussion. One quite obvious objection is that the original KS argument works for possessed values, not measured values, so the MKC argument, which turns on the finite precision of measurements, misses the mark. We might not be able to test observables which are exactly orthogonal or exactly alike in different tests, but it would be a strange HV interpretation that asserts that such components do not exist (see Cabello 1999). Of course, such a noncontextual HV proposal would be immune to the KS argument, but it would be forced to either deny that for every one of the continuously many directions in physical space there is an observable, or else deny that there are continuously many directions -- and neither denial seems very attractive.

In addition, the MKC argument is dissatisfying, since it exploits the finite precision of real measurements only in one of the above senses, but presupposes infinite precision in the other. MKC assume, for measured observables, that there is finite precision in the choice of different orthogonal triples, such that we cannot, in general, have exactly the same observable twice, as a member of two different triples. However, MKC still assume infinite precision, i.e. exact orthogonality, within the triple (otherwise the colouring constraints could find no application, at all). It has been claimed that this feature can be exploited to rebut the argument and to re-install contextualism (see Mermin 1999, Appleby 2000).

Finally, it can be shown that quantum probabilities vary continuously as we change directions in R3, so small imperfections of selection of observables that block the argument (but only for measured values!) in the single case will wash out in the long run (see Mermin 1999). This in itself does not constitute an argument, since in the colourable sets of observables in MKC's constructions probabilities also vary (in a sense) continuously.[15] We might, however, exploit Mermin's reasoning in the following way. Reconsider Clifton's set of eight directions (in Figure 3) leading to a colouring constraint for the outermost points which statistically contradicts the QM statistics by a fraction of 1/17. Now, starting from the colourable subset of directions constructed by MKC, we are unable to derive the constraint for the eight points, since these eight points do not lie in that set; i.e., as we move, in the colourable subset, from one mutually orthogonal triple of rays to the next, we never hit upon exactly the same ray again, but only to one approximating it arbitrarily closely. However, consider the following response. Assume that observables corresponding to the eight directions, though not lying in the colourable subset, exist and, according to the HV premise, all have values. Then we can derive Clifton's constraint for the outermost points. For these outermost points it is irrelevant whether, in an eventual empirical test we hit them exactly, for the Mermin argument says that, even if, in every single imperfect measurement, we only measure points nearby, we will, in the long-run better and better approximate the QM statistics for exactly the points in question - which means that we will better and better approach 1/17, while the HV assumption requires that we will better and better approach 0. (Recall also that this number can be pushed up to 1/3 by choosing a set of 13 directions!)

So, in sum it seems that, as long as we assume that there are continuously many QM observables

(corresponding to the continuum of directions in physical space), statistical tests building, e.g., on the Clifton 1993 or the Cabello/Alcaìne 1998 proposal remain entirely valid as empirical confirmations of the KS theorem. Since these statistical violations of the HV programme come about as contradictions of results of QM, VD, VR, and NC on the one hand, and QM and experiment on the other, the experimental data still force upon us the trilemma of giving up either VD or VR or NC. As we have seen, denial of value realism in the end becomes identical to a kind of contextualism, hence we really have only two options: (1) Giving up VD, either for all observables forbidden to have values in the orthodox interpretation (thus giving up the HV programme), or for a subset of these observables (as modal interpretations do). (2) Endorse a kind of contextualism. Moreover, as things presently stand, the choice between these two options seems not to be a matter of empirical testing, but one of pure philosophical argument.

Notes to The Kochen-Specker Theorem

Notes

[1] Note that if we understand the 'expectation' values deriving from the hidden states as what someone knowing such a state should expect as the average measurement result, then this claim is correct only given an assumption of faithful measurement (FM). FM is another typical assumption of a realist (or noncontextualist HV) interpretation of QM. The KS argument can be given without FM, since it makes claims about possessed values, not measured values. Only in statistical arguments, like von Neumann's and Clifton's, must FM be assumed. We suppress FM in the main text with the exception of Contextuality (see Section 5.3).

[2] See Bell (1966: 4) and Jammer (1974: 274, 304); see also Kochen and Specker (1967: 82/322, theorem 3) for a parallel example and criticism of von Neumann.

[3] Mermin is right insofar as Bell (1966) appeared before Kochen and Specker (1967). However, KS establish even the first step in the argument (two points being assigned different numbers (1 or 0) cannot be arbitrarily close) by an argument differing from Bell's proposal and refer to Specker (1960) which effectively establishes that step as a consequence of Gleason's theorem. So it is probably right to say that Specker and Bell independently saw and exploited that theorem.

[4] For a discussion of the relationship between contextuality and nonlocality, see Mermin (1990a) and Clifton (1993).

[5] See Kochen and Specker (1967: 71-72/310-11).

[6] By elementary vector algebra, viz.: $\mathbf{a}\cdot\mathbf{b}=|a|\ |b| \cos \varphi$, where $\mathbf{a}\cdot\mathbf{b}$ is the inner product of vectors **a** and **b** and φ is the angle between them.

[7] Both arguments, i.e., von Neumann's and Clifton's, presuppose faithful measurement (FM) (see also fn 1). Indeed, an eventual failure of FM would be the natural way to explain why a certain constraint on possessed values does not show up in the measurement statistics.

[8] A state of a spin-1 particle where prob($v(S_x^2)=0$)=1 is $|S_x=0\rangle$. Expanding this state in the eigenvectors of $S_{x'}$ yields

$|S_x=0\rangle=$

$$\cos \wp\ (1 + \sin^2 \wp)^{-1/2}\ |S_x{}' = 0\rangle + \sin \wp\ (1 + \sin^2 \wp)^{-1/2}\ (|S_x{}' = -1\rangle - |S_x{}' = +1\rangle)$$

Now, with $\cos \wp = 1/3$, we get:

$$\begin{aligned} \text{prob}(v(S_x{}'^2) = 0) &= \text{prob}(v(S_x{}') = 0) \\ &= (\cos \wp)^2 / (1 + \sin^2 \wp) \\ &= 1/9\ (1 + 8/9)^{-1} \\ &= 1/17 \end{aligned}$$

[9] See Redhead (1987: 121). See also Kochen and Specker (1967: 64/299, eq. 4) and Fine and Teller (1978: 631) where the principle appears under the name "functional relation condition".

[10] It is not exactly true that the QM formalism prescribes *any* observable to have a value. In fact, the formalism itself is entirely silent about values, apart from the statistical predictions it entails via the statistical algorithm (see Redhead 1987: 8). But a crucial assumption of orthodox interpretations is the eigenstate-eigenvalue link (see Fine 1973: 20): Observable A on a system has value a_k iff the system is in state $|a_k\rangle$. The 'if' direction of this principle, which leads to a minimum of value ascriptions, is endorsed by modal interpreters (this direction is equivalent to the Eigenvector Rule in Redhead 1987: 73, 120). What they usually deny is the 'only if' direction, which thereby allows them to attribute values to more observables than allowed by orthodox interpretations.

[11] This is Redhead's (1987: 135-36) construal of a proposal by Fine (1974).

[12] See Fine and Teller (1978: 636), Redhead (1987: 138) and references therein.

[13] What we mean here is the following. A definition of observable f(A) (or observable A + B, or observable A▪B, both constructed from observables A and B) would be that it is an observable which takes a value calculated by measuring v(A) (or measuring v(A) and v(B)) and applying f to the result (or calculating $v(A) + v(B)$, or calculating $v(A)\ v(B)$). FUNC, the Sum Rule and the Product Rule, as restricted to one measurement context, trivially repeat these definitions, and there obviously is no point in testing, e.g., whether $v(A \cdot B)$ really equals $v(A)\ v(B)$, if the former expression is defined by the latter.

[14] It should be noted here that Meyer and Clifton / Kent have quite different intentions. Meyer really criticizes the KS argument against HV as being invalid. Clifton and Kent, however, by presenting HV constructions along Meyer's lines do not mean to bring forth a physically plausible HV theory, but only intend to show that QM statistics for KS-type sets of observables can be *simulated* by a noncontextual HV model, thus in an entirely classical way.

[15] The proviso 'in a sense' comes from the fact that a colourable subset of the set of observables

corresponding to all directions in R3, since it is a proper subset of the latter, is not itself continuous in the intuitive sense. We can, however, define a probability function from such a colourable subset into [0, 1] which obeys the usual continuity definition of elementary calculus.

Supplement to The Kochen-Specker Theorem

Proof of VC1

We exploit two mathematical facts about projection operators P_i:

(A) $P_i^2 = P_i$ (the P_i are 'idempotent');

(B) If H is a Hilbert space of denumerable dimension, and if the P_i are operators projecting on q_i, where the set $\{q_i\}$ forms an orthonormal basis of H, then $\Sigma_i P_i = I$ (where I is the identity operator) (the P_i form 'a resolution of the identity').

Consider now an arbitrary state $|\psi>$ and an arbitrary nondegenerate operator Q on H3, its eigenvectors $|q_1>$, $|q_2>$, $|q_3>$, and projection operators P_1, P_2, P_3 whose ranges are the rays spanned by these vectors. The eigenvectors form an orthonormal basis, thus, by (B):

$$P_1 + P_2 + P_3 = I$$

Now, P_1, P_2, P_3 are compatible, so from assumption KS2 (a) (Sum Rule):

$$(P_1) + v(P_2) + v(P_3) = v(I)$$

Now, from KS2 (b) (Product Rule) and (A):

$$v(P_i)^2 = v(P_i^2) = v(P_i)$$
$$\Rightarrow v(P_i) = 1 \text{ or } 0$$

Now, assume an observable R such that $v(R) \neq 0$ in state $|\psi>$. From this assumption and KS2 (b) (Product Rule):

$$v(R) = v(I\,R) = v(I)\,v(R)$$
$$\Rightarrow v(I) = 1$$

Hence:

$$\text{(VC1)}\quad v(P_1) + v(P_2) + v(P_3) = 1$$

where $v(P_i) = 1$ or 0, for $i = 1, 2, 3$.

Supplement to The Kochen-Specker Theorem

Proof of VC2

Let S_x, S_y, S_z be the usual angular momentum operators satisfying $[S_x, S_y] = i\, S_z$, and define $S^2 := S_x^2 + S_y^2 + S_z^2$. It can be shown that the eigenvalues of S^2 are $s(s + 1)$ where s is an integer or half-integer.

Now let s=1. Then it follows (see e.g. Kochen and Specker 1967: 308, Redhead 1987: 37-38) that S_x^2, S_y^2, S_z^2 are all mutually commuting and that:

$$S_x^2 + S_y^2 + S_z^2 = 2I,$$

where I is the identity operator. Now, from KS2 (a) (Sum Rule):

$$v(S_x^2) + v(S_y^2) + v(S_z^2) = 2v(I)$$

Now, assume an observable R such that $v(R) \neq 0$ in state $|\psi\rangle$. From this assumption and KS2 (b) (Product Rule):

$$v(R) = v(I\, R) = v(I)\, v(R)$$
$$\Rightarrow v(I) = 1$$

Hence:

$$\text{(VC2)} \quad v(S_x^2) + v(S_y^2) + v(S_z^2) = 2$$

where $v(S_i^2) = 1$ or 0, for $i = x, y, z$.

Stanford Encyclopedia of Philosophy
Supplement to The Kochen-Specker Theorem

Proof of Step 1

A given point a_0 on the unit sphere E uniquely picks out a unit vector from the origin to a_0 which in turn uniquely picks out a ray in R3 through the origin and a_0. We here work with unit vectors, since this involves no loss of generality. We write a_0, a_1, ... for points and $u(a_0)$, $u(a_1)$, ... for the corresponding unit vectors. We call a KS diagram realizable on E, if there is a 1:1 mapping of points of E, and thus of vectors in R3, to vertices of the diagram such that the orthogonality relations in the diagram -- namely, vertices joined by a straight line represent mutually orthogonal points -- are satisfied by the corresponding vectors.

We now show (see Kochen and Specker 1967: , Redhead 1987: 126):

> If vectors $u(a_0)$ and $u(a_9)$, corresponding to points a_0 and a_9 of the following ten-point KS graph Γ_1 are separated by an angle θ with $0 \leq \theta \leq \sin^{-1}(1/3)$, then Γ_1 is realizable.

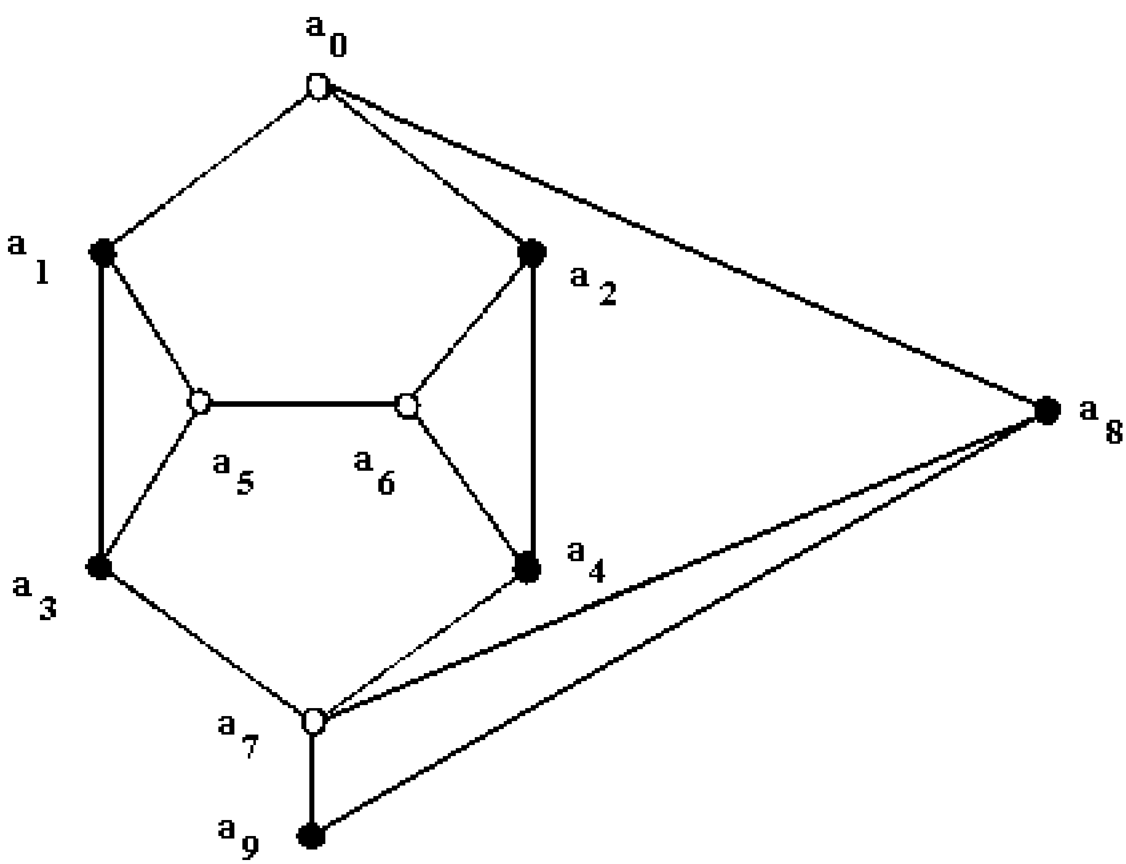

Figure 4: Ten-point KS graph Γ_1

Suppose that θ, the angle between $u(a_0)$ and $u(a_9)$, is any acute angle. Since $u(a_8)$ is orthogonal to $u(a_0)$ and $u(a_9)$, and $u(a_7)$ also is orthogonal to $u(a_9)$, $u(a_7)$ must lie in the plane defined by $u(a_0)$ and $u(a_9)$. Moreover, the direction of $u(a_7)$ can be chosen such that, if φ is the angle between $u(a_0)$ and $u(a_7)$, then $\varphi = \pi/2 - \theta$.

Now, let $u(a_5) = \mathbf{i}$ and $u(a_6) = \mathbf{k}$ and choose a third vector $\mathbf{j}$ such that $\mathbf{i}$, $\mathbf{j}$, $\mathbf{k}$ form a complete set of orthonormal vectors. Then $u(a_1)$, being orthogonal to $\mathbf{i}$, may be written as:

$$u(a_1) = (\mathbf{j} + x\mathbf{k})\,(1 + x^2)^{-1/2}$$

for a suitable real number x, and similarly $u(a_2)$, being orthogonal to $\mathbf{k}$, may be written as:

$$u(a_2) = (\mathbf{i} + y\mathbf{j})\,(1 + y^2)^{-1/2}$$

for a suitable real number y. But now the orthogonality relations in the diagram yield:

$$u(a_3) = u(a_5) \times u(a_1) = (-x\mathbf{j} + \mathbf{k})\,(1 + x^2)^{-1/2}$$

$$u(a_4) = u(a_2) \times u(a_6) = (y\mathbf{i} - \mathbf{j})\,(1 + y^2)^{-1/2}$$

Now, $u(a_0)$ is orthogonal to $u(a_1)$ and $u(a_2)$, so:

$$u(a_0) = u(a_1) \times u(a_2) / (\,|\,u(a_1) \times u(a_2)\,|\,) = (-xy\mathbf{i} + x\mathbf{j} - \mathbf{k})\,(1 + x^2 + x^2 y^2)^{-1/2}$$

Similarly, $u(a_7)$ is orthogonal to $u(a_3)$ and $u(a_4)$, so:

$$u(a_7) = u(a_4) \times u(a_3) / (\,|\,u(a_4) \times u(a_3)\,|\,) = (-\mathbf{i} - y\mathbf{j} - xy\mathbf{k})\,(1 + y^2 + x^2 y^2)^{-1/2}$$

Recalling now that the inner product of two unit vectors just equals the cosine of the angle between them, we get:

$$u(a_0)\,u(a_7) = \cos\varphi = xy[(1 + x^2 + x^2 y^2)\,(1 + y^2 + x^2 y^2)]^{-1/2}$$

Thus:

$$\sin\theta = xy[(1 + x^2 + x^2 y^2)\,(1 + y^2 + x^2 y^2)]^{-1/2}$$

This expression achieves a maxium value of 1/3 for $x = y = \pm 1$. Hence, the diagram is realizable, if $0 \leq$

$\theta \leq \sin^{-1}(1/3)$, or, equivalently if $0 \leq \sin\theta \leq 1/3$.

Derivation of Sum Rule and Product Rule from FUNC

The three principles, in full detail, are:

> **FUNC:** Let **A** be a self-adjoint operator associated with observable A, let f: **R**→**R** be an arbitrary function, such that **f(A)** is self-adjoint operator, and let | f > be an arbitrary state; then **f(A)** is associated uniquely with an observable f(A) such that:
>
> $v(f(A))_{|\varphi\rangle} = f(v(A))_{|\varphi\rangle}$
>
> **Sum Rule:** If **A** and **B** are commuting self-adjoint operators corresponding to observables A and B, respectively, then A + B is the unique observable corresponding to the self-adjoint operator **A + B** and
>
> $v(A + B)_{|\varphi\rangle} = v(A)_{|\varphi\rangle} + v(B)_{|\varphi\rangle}$
>
> **Product Rule:** If **A** and **B** are commuting self-adjoint operators corresponding to observables A and B, respectively, then if A · B is the unique observable corresponding to the self-adjoint operator **A** · **B** and
>
> $v(AB)_{|\varphi\rangle} = v(A)_{|\varphi\rangle} \cdot v(B)_{|\varphi\rangle}$

In order to derive Sum Rule and Product Rule from FUNC, we use the following mathematical fact: Let **A** and **B** be commuting operators, then there is a maximal operator **C** and there are functions f, g such that **A** = f(**C**) and **B** = g(**C**).

So, for two commuting operators **A**, **B**:

> Since **A** = f(**C**) and **B** = g(**C**), there is a function h = f+g, such that **A + B** = h(**C**).

Therefore:

$$
\begin{aligned}
v(A + B)_{|\varphi\rangle} &= h(v(C)_{|\varphi\rangle}) && \text{(by FUNC)} \\
&= f(v(C)_{|\varphi\rangle}) + g(v(C)_{|\varphi\rangle}) \\
&= v(f(C))_{|\varphi\rangle} + v(g(C))_{|\varphi\rangle} && \text{(by FUNC)}
\end{aligned}
$$

$= \; v(A)_{|\varphi\rangle} + v(B)_{|\varphi\rangle}$ (Sum Rule)

Similarly:

Since $\mathbf{\underline{A}} = f(\mathbf{\underline{C}})$ and $\mathbf{\underline{B}} = g(\mathbf{\underline{C}})$, there is a function $k = f \cdot g$, such that $\mathbf{\underline{A}} \cdot \mathbf{\underline{B}} = k(\mathbf{\underline{C}})$.

Therefore:

$$
\begin{aligned}
v(A \cdot B)_{|\varphi\rangle} &= k(v(C)_{|\varphi\rangle}) && \text{(by FUNC)} \\
&= f(v(C)_{|\varphi\rangle}) \cdot g(v(C)_{|\varphi\rangle}) && \\
&= v(f(C))_{|\varphi\rangle} \cdot v(g(C))_{|\varphi\rangle} && \text{(by FUNC)} \\
&= v(A)_{|\varphi\rangle} \cdot v(B)_{|\varphi\rangle} && \text{(Product Rule)}
\end{aligned}
$$

Stanford Encyclopedia of Philosophy
Supplement to The Kochen-Specker Theorem

Derivation of STAT FUNC

The result is proved for a pure state and a non-degenerate discrete observable A with eigenvalues a_i.

We first rewrite the statistical algorithm for projection operators:

$$\textbf{(1)}\quad \text{prob}\,(v\,(A)^{|\psi>} = a_k) = \text{Tr}\,(P_{|a_k>} \cdot P_{|\psi>})$$

For an arbitrary function f: **R** → **R** (where **R** is the set of real numbers) we define the function of an observable A as:

$$f(A) =_{\text{Def}} \Sigma_i\, f(a_i)\, P_{|a_i>}$$

Moreover, we introduce the characteristic function χ_a of a number a as:

$$\begin{aligned} \chi_a(x) &= 1 \text{ for } x = a \\ &= 0 \text{ for } x \neq a \end{aligned}$$

As a result, we can rewrite a project operator $P_{|a_k>}$ as:

$$\textbf{(2)}\quad P_{|a_k>} = \chi_{a_k}(A)$$

and thus the statistical algorithm as:

$$\text{prob}\,(v\,(A)^{|\psi>} = a_k) = \text{Tr}\,(\chi_{a_k}(A) \cdot P_{|\psi>})$$

We also use a simple mathematical property of characteristic functions:

$$\chi_a(f(x)) = \chi_{f^{-1}(a)}(x)$$

whence we can also write:

(3) $\chi_a(f(A)) = \chi_{f^{-1}(a)}(A)$

Then:

$$\begin{aligned}
\text{prob}\,(v(f(A))^{|\phi>} = b) &= \text{Tr}\,(P_{|b>} \cdot P_{|\phi>}) && \text{(by (1))} \\
&= \text{Tr}\,(\chi_b\,(f(A)) \cdot P_{|\phi>}) && \text{(by (2))} \\
&= \text{Tr}\,((\chi_{f^{-1}(b)}\,(A) \cdot P_{|\phi>}) && \text{(by (3))} \\
&= \text{Tr}\,(P_{|f^{-1}(b)>} \cdot P_{|\phi>}) && \text{(by (2))} \\
&= \text{prob}\,(v\,(A)^{|\phi>} = f^{-1}(b)) && \text{(by (1))}
\end{aligned}$$

Hence:

$$\text{prob}\,(v(f(A))^{|\phi>} = b) = \text{prob}\,(v\,(A)^{|\phi>} = f^{-1}(b))$$

Now since

$$v\,(A) = f^{-1}(b) \quad \Leftrightarrow \quad f\,(v\,(A)) = b$$

$$\text{prob}\,(v(f(A))^{|\phi>} = b) = \text{prob}\,(f(v\,(A))^{|\phi>} = b)$$

which is STAT FUNC.

STAT FUNC from FUNC

Indeed, STAT FUNC follows immediately from FUNC. Given A, f, and $|\varphi\rangle$ as defined in FUNC, we have:

$$v(f(A))_{|\varphi\rangle} = f(v(A))_{|\varphi\rangle},$$

where f(A) is a new observable. Now, by the statistical algorithm:

> **STAT FUNC:** Given A, f, and $|\varphi\rangle$ as defined in FUNC, then, for an arbitrary real number b:
>
> $$\text{prob}[v(f(A))_{|\varphi\rangle} = b] = \text{prob}[f(v(A))_{|\varphi\rangle} = b]$$

Quantum Logic and Quantum Probability

At its core, quantum mechanics can be regarded as a non-classical probability calculus resting upon a non-classical propositional logic. More specifically, in quantum mechanics each probability-bearing proposition of the form "the value of physical quantity *A* lies in the range *B*" is represented by a projection operator on a Hilbert space **H**. These form a non-Boolean -- in particular, non-distributive -- orthocomplemented lattice. Quantum-mechanical states correspond exactly to probability measures (suitably defined) on this lattice.

What are we to make of this? Some have argued that the empirical success of quantum mechanics calls for a revolution in logic itself. This view is associated with the demand for a realistic interpretation of quantum mechanics, i.e., one not grounded in any primitive notion of measurement. Against this, there is a long tradition of interpreting quantum mechanics operationally, that is, as being precisely a theory of measurement. On this latter view, it is not surprising that a "logic" of measurement-outcomes, in a setting where not all measurements are compatible, should prove not to be Boolean. Rather, the mystery is why it should have the *particular* non-Boolean structure that it does in quantum mechanics. A substantial literature has grown up around the programme of giving some independent motivation for this structure -- ideally, by deriving it from more primitive and plausible axioms governing a generalized probability theory.

1. Quantum Mechanics as a Probability Calculus

It is uncontroversial (though remarkable) that the formal apparatus of quantum mechanics reduces neatly to a generalization of classical probability in which the role played by a Boolean algebra of events in the latter is taken over by the "quantum logic" of projection operators on a Hilbert space.[1] Moreover, the usual statistical interpretation of quantum mechanics asks us to take this generalized quantum probability theory quite literally -- that is, not as merely a formal analogue of its classical counterpart, but as a genuine doctrine of chances. In this section, I survey this quantum probability theory and its supporting quantum logic.[2]

> [For further background on Hilbert spaces, see Supplement 1: The Basic Theory of Hilbert Spaces. For further background on ordered sets and lattices, see Supplement 2: The Basic Theory of Ordering Relations. Concepts and results explained these supplements will be used freely in what follows.]

Quantum Probability in a Nutshell

The quantum-probabilistic formalism, as developed by von Neumann [1932], assumes that each physical system is associated with a (separable) Hilbert space **H**, the unit vectors of which correspond to possible physical *states* of the system. Each "observable" real-valued random quantity is represented by a self-adjoint operator A on **H**, the spectrum of which is the set of possible values of A. If u is a unit vector in the domain of A, representing a state, then the expected value of the observable represented by A in this state is given by the inner product $\langle Au,u \rangle$. The observables represented by two operators A and B are commensurable iff A and B commute, i.e., $AB = BA$. (For further discussion, see the entry on Quantum Mechanics.)

The "Logic" of Projections

As stressed by von Neumann, the {0,1}-valued observables may be regarded as encoding propositions about -- or, to use his phrasing, properties of -- the state of the system. It is not difficult to show that a self-adjoint operator P with spectrum contained in the two-point set {0,1} must be a projection; i.e., $P^2 = P$. Such operators are in one-to-one correspondence with the closed subspaces of **H**. Indeed, if P is a projection, its range is closed, and any closed subspace is the range of a unique projection. If u is any unit vector, then $\langle Pu,u \rangle = ||Pu||^2$ is the expected value of the corresponding observable in the state represented by u. Since this is {0,1}-valued, we can interpret this as the *probability* that a measurement of the observable will produce the "affirmative" answer 1. In particular, the affirmative answer will have probability 1 if and only if $Pu = u$; that is, u lies in the range of P. Von Neumann concludes that

> … the relation between the properties of a physical system on the one hand, and the projections on the other, makes possible a sort of logical calculus with these. However, in

contrast to the concepts of ordinary logic, this system is extended by the concept of "simultaneous decidability" which is characteristic for quantum mechanics [1932, p. 253].

Let's examine this "logical calculus" of projections. Ordered by set-inclusion, the closed subspaces of **H** form a complete lattice, in which the meet (greatest lower bound) of a set of subspaces is their intersection, while their join (least upper bound) is the closed span of their union. Since a typical closed subspace has infinitely many complementary closed subspaces, this lattice is not distributive; however, it is orthocomplemented by the mapping

$$\mathbf{M} \rightarrow \mathbf{M}\perp = \{v \in \mathbf{H} \mid \forall u \in \mathbf{M}(\langle v,u \rangle = 0)\}.$$

In view of the above-mentioned one-one correspondence between closed subspaces and projections, we may impose upon the set $L(\mathbf{H})$ the structure of a complete orthocomplemented lattice, defining $P \leq Q$, where $ran(P) \subseteq ran(Q)$ and $P' = 1 - P$ (so that $ran(P') = ran(P)\perp$). It is straightforward that $P \leq Q$ just in case $PQ = QP = P$. More generally, if $PQ = QP$, then $PQ = P \wedge Q$, the meet of P and Q in $L(\mathbf{H})$; also in this case their join is given by $P \vee Q = P+Q - PQ$.

1.1 Lemma:
Let P and Q be projection operators on the Hilbert space **H**. The following are equivalent:

a. $PQ = QP$
b. The sublattice of $L(\mathbf{H})$ generated by P, Q, P' and Q' is Boolean
c. P, Q lie in a common Boolean sub-ortholattice of $L(\mathbf{H})$.

Adhering to the idea that commuting observables -- in particular, projections -- are simultaneously measurable, we conclude that the members of a Boolean "block" (that is, a Boolean sub-ortholattice) of $L(\mathbf{H})$ are simultaneously testable. This suggests that we can maintain a classical logical interpretation of the meet, join and orthocomplement as applied to commuting projections.

Probability Measures and Gleason's Theorem

The foregoing discussion motivates the following. Call projections P and Q *orthogonal*, and write $P \perp Q$ iff $P \leq Q'$. Note that $P \perp Q$ iff $PQ = QP = 0$. If P and Q are orthogonal projections, then their join is simply their sum; traditionally, this is denoted $P \oplus Q$. We denote the identity mapping on **H** by **1**.

1.2 Definition:
A (countably additive) *probability measure* on $L(\mathbf{H})$ is a mapping $\mu : L \rightarrow [0,1]$ such that $\mu(\mathbf{1}) = 1$ and, for any sequence of pair-wise orthogonal projections P_i, $i = 1,2,...$

$$\mu(\oplus_i P_i) = \Sigma_i \mu(P_i)$$

Here is one way in which we can manufacture a probability measure on $L(\mathbf{H})$. Let u be a unit vector of $\mathbf{H}$, and set $\mu_u(P) = \langle Pu,u \rangle$. This gives the usual quantum-mechanical recipe for the probability that P will have value 1 in the state u. Note that we can also express μ_u as $\mu_u(P) = Tr(P\,P_u)$, where P_u is the one-dimensional projection associated with the unit vector u.

More generally, if μ_i, i=1,2,…, are probability measures on $L(\mathbf{H})$, then so is any "mixture", or convex combination $\mu = \Sigma_i\, t_i \mu_i$ where $0 \leq t_i \leq 1$ and $\Sigma_i\, t_i = 1$. Given any sequence $u_1, u_2,\ldots$, of unit vectors, let $\mu_i = \mu_{u_i}$ and let $P_i = P_{u_i}$. Forming the operator

$$W = t_1 P_1 + t_2 P_2 + \ldots ,$$

one sees that

$$\mu(P) = t_1 Tr(P\,P_1) + t_2 Tr(P\,P_2) + \ldots = Tr(WP)$$

An operator expressible in this way as a convex combination of one-dimensional projections in is called a *density operator*. Thus, every density operator W gives rise to a countably additive probability measure on $L(\mathbf{H})$. The following striking converse, due to A. Gleason [1957], shows that the theory of probability measures on $L(\mathbf{H})$ is co-extensive with the theory of (mixed) quantum mechanical states on $\mathbf{H}$:

> **1.3 Gleason's Theorem**:
> Let $\mathbf{H}$ have dimension > 2. Then every countably additive probability measure on $L(\mathbf{H})$ has the form $\mu(P) = Tr(WP)$, for a density operator W on $\mathbf{H}$.

An important consequence of Gleason's Theorem is that $L(\mathbf{H})$ does not admit any probability measures having only the values 0 and 1. To see this, note that for any density operator W, the mapping $u \rightarrow \langle Wu,u \rangle$ is continuous on the unit sphere of $\mathbf{H}$. But since the latter is connected, no continuous function on it can take only the two values 0 and 1. This result is often taken to rule out the possibility of 'hidden variables' -- an issue taken up in more detail in section 6.

The Reconstruction of QM

From the single premise that the "experimental propositions" associated with a physical system are encoded by projections in the way indicated above, one can reconstruct the rest of the formal apparatus of quantum mechanics. The first step, of course, is Gleason's theorem, which tells us that probability measures on $L(\mathbf{H})$ correspond to density operators. There remains to recover, e.g., the representation of "observables" by self-adjoint operators, and the dynamics (unitary evolution). The former can be recovered with the help of the Spectral theorem and the latter with the aid of a deep theorem of E. Wigner on the projective representation of groups. See also R. Wright [1980]. A detailed outline of this reconstruction (which involves some distinctly non-trivial mathematics) can be found in the book of

Varadarajan [1985]. The point to bear in mind is that, once the quantum-logical skeleton $L(\mathbf{H})$ is in place, the remaining statistical and dynamical apparatus of quantum mechanics is essentially fixed. In this sense, then, quantum mechanics -- or, at any rate, its mathematical framework -- *reduces to* quantum logic and its attendant probability theory.

2. Interpretations of Quantum Logic

The reduction of QM to probability theory based on $L(\mathbf{H})$ is mathematically compelling, but what does it tell us about QM --- or, assuming QM to be a correct and complete physical theory, about the world? How, in other words, are we to interpret the quantum logic $L(\mathbf{H})$? The answer will turn on how we unpack the phrase, freely used above,

> (*) The value of the observable A lies in the range B.

One possible reading of (*) is *operational*: "measurement of the observable A would yield (or will yield, or has yielded) a value in the set B ". On this view, projections represent statements about the possible results of measurements. This sits badly with realists of a certain stripe, who, shunning reference to 'measurement', prefer to understand (*) as a *property ascription*: "the system has a certain categorical property, which corresponds to the observable A having, independently of any measurement, a value in the set B". (One must be careful in how one understands this last phrase, however: construed incautiously, it seems to posit a hidden-variables interpretation of quantum mechanics of just the sort ruled out by Gleason's Theorem. I will have more to say about this below.)

Realist Quantum Logic

The interpretation of projection operators as representing the properties of a physical system is already explicit in von Neumann's *Grundlagen.*. However, the logical operations discussed there apply only to commuting projections, which are identified with simultaneously decidable propositions. In [1936] von Neumann and Birkhoff took a step further, proposing to interpret the lattice-theoretic meet and join of projections as their conjunction and disjunction, *whether or not* they commute. Immediately this proposal faces the problem that the lattice $L(\mathbf{H})$ is not distributive, making it impossible to give these 'quantum' connectives a truth-functional interpretation. Undaunted, von Neumann and Birkhoff suggested that the empirical success of quantum mechanics as a framework for physics casts into doubt the universal validity of the distributive laws of propositional logic. Their phrasing remains cautious:

> Whereas logicians have usually assumed that properties … of negation were the ones least able to withstand a critical analysis, the study of mechanics points to the distributive identities … as the weakest link in the algebra of logic. [1937, p. 839]

In the 1960s and early 1970s, this thesis was advanced rather more aggressively by a number of authors, including especially David Finkelstein and Hilary Putnam, who argued that quantum mechanics requires

a revolution in our understanding of logic *per se*. According to Putnam [1968], “Logic is as empirical as geometry. … We live in a world with a non-classical logic.”

For Putnam, the elements of $L(\mathbf{H})$ represent categorical properties that an object possesses, or does not, independently of whether or not we look. Inasmuch as this picture of physical properties is confirmed by the empirical success of quantum mechanics, we must, on this view, accept that the way in which physical properties actually hang together is not Boolean. Since logic is, for Putnam, very much the study of how physical properties actually hang together, he concludes that classical logic is simply mistaken: the distributive law is not universally valid.

Classically, if S is the set of states of a physical system, then *every* subset of S corresponds to a categorical property of the system, and vice versa. In quantum mechanics, the state space is the (projective) unit sphere $S = S(\mathbf{H})$ of a Hilbert space. However, not all subsets of S correspond to quantum-mechanical properties of the system. The latter correspond only to subsets of the special form $S \cap \mathbf{M}$, for $\mathbf{M}$ a closed linear subspace of $\mathbf{H}$. In particular, only subsets of this form are assigned probabilities. This leaves us with two options. One is to take only these special properties as ‘real’ (or ‘physical’, or ‘meaningful’), regarding more general subsets of S as corresponding to no real categorical properties at all. The other is to regard the ‘quantum’ properties as a small subset of the set of all physically (or at any rate, metaphysically) reasonable, but not necessarily *observable*, properties of the system. On this latter view, the set of *all* properties of a physical system is entirely classical in its logical structure, but we decline to assign probabilities to the non-observable properties.[3]

This second position, while certainly not inconsistent with realism *per se*, turns upon a distinction involving a notion of "observation", "measurement", "test", or something of this sort -- a notion that realists are often at pains to avoid in connection with fundamental physical theory. Of course, any realist account of a statistical physical theory such as quantum mechanics will ultimately have to render up some explanation of how measurements are supposed to take place. That is, it will have to give an account of which physical interactions between "object" and "probe" systems count as measurements, and of how these interactions cause the probe system to evolve into final ‘outcome-states’ that correspond to -- and have the same probabilities as -- the outcomes predicted by the theory. This is notorious *measurement problem* .

In fact, Putnam advanced his version of quantum-logical realism as offering a (radical) dissolution of the measurement problem: According to Putnam, the measurement problem (and indeed every other quantum-mechanical "paradox") arises through an improper application of the distributive law, and hence *disappears* once this is recognized. This proposal, however, is widely regarded as mistaken.

As mentioned above, realist interpretations of quantum mechanics must be careful in how they construe the phrase "the observable A has a value in the set B ". The simplest and most traditional proposal -- often dubbed the "eigenstate-eigenvalue link" (Find 1973) -- is that (*) holds if and only if a measurement of A yields a value in the set B with certainty, i.e., with (quantum-mechanical!) probability 1. While this certainly gives a realist interpretation of (*) [4], it does not provide a solution to the measurement

problem. Indeed, we can use it to give a sharp formulation of that problem: even though *A* is certain to yield a value in *B* when measured, unless the quantum state is an eigenstate of the measured observable *A*, the system does not possess any categorical property corresponding to *A*'s having a specific value in the set *B*. Putnam seems to assume that a realist interpretation of (*) should consist in assigning to *A* some unknown value within *B*, for which quantum mechanics yields a non-trivial probability. However, an attempt to make such assignments simultaneously for all observables runs afoul of Gleason's Theorem. [5]

Operational Quantum Logic

If we put aside scruples about 'measurement' as a primitive term in physical theory, and accept a principled distinction between 'testable' and non-testable properties, then the fact that *L*(**H**) is not Boolean is unremarkable, and carries no implication about logic *per se*. Quantum mechanics is, on this view, a theory about the possible statistical distributions of outcomes of certain measurements, and its non-classical 'logic' simply reflects the fact that not all observable phenomena can be observed simultaneously. Because of this, the set of probability-bearing events (or propositions) is *less* rich than it would be in classical probability theory, and the set of possible statistical distributions, accordingly, less tightly constrained. That some 'non-classical' probability distributions allowed by this theory are actually manifested in nature is perhaps surprising, but in no way requires any deep shift in our understanding of logic or, for that matter, of probability.

This is hardly the last word, however. Having accepted all of the above, there still remains the question of *why* the logic of measurement outcomes should have the very special form *L*(**H**), and never anything more general.[6] This question entertains the idea that the formal structure of quantum mechanics may be *uniquely determined* by a small number of reasonable assumptions, together perhaps with certain manifest regularities in the observed phenomena. This possibility is already contemplated in von Neumann's *Grundlagen* (and also his later work in continuous geometry), but first becomes explicit -- and programmatic -- in the work of George Mackey [1957, 1963]. Mackey presents a sequence of six axioms, framing a very conservative generalized probability theory, that underwrite the construction of a 'logic' of experimental propositions, or, in his terminology, 'questions', having the structure of a sigma-orthomodular poset. The outstanding problem, for Mackey, was to explain why this poset *ought to* be isomorphic to *L*(**H**):

> Almost all modern quantum mechanics is based implicitly or explicitly on the following assumption, which we shall state as an axiom:
>
> > Axiom VII: The partially ordered set of all questions in quantum mechanics is isomorphic to the partially ordered set of all closed subspaces of a separable, infinite dimensional Hilbert space.
>
> This axiom has rather a different character from Axioms I through VI. These all had some degree of physical naturalness and plausibility. Axiom VII seems entirely ad hoc. Why do

> we make it? Can we justify making it? … Ideally, one would like to have a list of physically plausible assumptions from which one could deduce Axiom VII. Short of this one would like a list from which one could deduce a set of possibilities for the structure … all but one of which could be shown to be inconsistent with suitably planned experiments. [19, pp. 71-72]

Since Mackey's writing there has grown up an extensive technical literature exploring variations on his axiomatic framework in an effort to supply the missing assumptions. The remainder of this article presents a brief survey of the current state of this project.

3. Generalized Probability Theory

Rather than restate Mackey's axioms verbatim, I shall paraphrase them in the context of an approach to generalized probability theory due to D. J. Foulis and C. H. Randall having -- among the many more or less homologous approaches available[7] -- certain advantages of simplicity and flexibility. References for this section are [Foulis, Greechie and Ruttimann 1992, Foulis, Piron and Randall 1983, Foulis and Randall 1982, Randall and Foulis 1983; see also Gudder 1985 and Wilce 2000b for surveys.]

Discrete Classical Probability Theory

It will be helpful to begin with a review of classical probability theory**.** In its simplest formulation, classical probability theory deals with a (discrete) set E of mutually exclusive outcomes, as of some measurement, experiment, etc., and with the various *probability weights* that can be defined thereon --- that is, with mappings $\omega : E \rightarrow [0,1]$ summing to 1 over E.[8]

Notice that the set $\Delta(E)$ of all probability weights on E is *convex*, in that, given any sequence $\omega_1, \omega_2, \ldots$ of probability weights and any sequence $t_1, t_2, \ldots$ of non-negative real numbers summing to one, the convex sum or 'mixture' $t_1\omega_1 + t_2\omega_2 + \ldots$ (taken pointwise on E) is again a probability weight. The extreme points of this convex set are exactly the "point-masses" $\delta(x)$ associated with the outcomes $x \in E$:

$$\delta(x)(y) = 1 \text{ if } x = y, \text{ and } 0 \text{ otherwise.}$$

Thus, $\Delta(E)$ is a *simplex*: each point $\omega \in \Delta(E)$ is representable in a unique way as a convex combination of extreme points, namely:

$$\omega = \sum \omega(x)\delta(x)$$

We need also to recall the concept of a *random variable*. If E is an outcome set and V, some set of 'values' (real numbers, pointer-readings, or what not), a *V-valued random variable* is simply a mapping f

: $E \to V$. The heuristic (but it need only be taken as that) is that one ‘measures’ the random variable f by ‘performing’ the experiment represented by E and, upon obtaining the outcome $x \in E$, recording $f(x)$ as the measured value. Note that if V is a set of real numbers, or, more generally, a subset of a vector space, we may define the *expected value* of f in a state $\omega \in \Delta(E)$ by:

$$E(f,\omega) = \sum_{x \in E} f(x)\omega(x).$$

Test Spaces

A very natural direction in which to generalize discrete classical probability theory is to allow for a multiplicity of outcome-sets, each representing a different ‘experiment’. To formalize this, let’s agree that a *test space* is a non-empty collection A of non-empty sets $E,F,\ldots$, each construed as a discrete outcome-set as in classical probability theory. Each set $E \in \mathcal{A}$ is called a *test*. The set $X = \bigcup\mathcal{A}$ of all outcomes of all tests belonging to $\mathcal{A}$ is called the *outcome space* of $\mathcal{A}$. Notice that we allow distinct tests to overlap, i.e., to have outcomes in common.[9]

If $\mathcal{A}$ is a test space with outcome-space X, a *state* on $\mathcal{A}$ is a mapping $\omega : X \to [0,1]$ such that $\Sigma_{x \in E}\, \omega(x) = 1$ for every test $E \in \mathcal{A}$. Thus, a state is a consistent assignment of a probability weight to each test -- consistent in that, where two distinct tests share a common outcome, the state assigns that outcome the same probability whether it is secured as a result of one test or the other. (This may be regarded as a normative requirement on the outcome-identifications implicit in the structure of $\mathcal{A}$: if outcomes of two tests are not equiprobable in all states, they ought not to be identified.) The set of all states on $\mathcal{A}$ is denoted by $\Omega(\mathcal{A})$. This is a convex set, but in contrast to the situation in discrete classical probability theory, it is generally not a simplex.

The concept of a random variable admits several generalizations to the setting of test spaces. Let us agree that a *simple (real-valued) random variable* on a test space $\mathcal{A}$ is a mapping $f : E \to \mathbf{R}$ where E is a test in $\mathcal{A}$. We define the *expected value* of f in a state $\omega \in \Omega(\mathcal{A})$ in the obvious way, namely, as the expected value of f with respect to the probability weight obtained by restricting ω to E (provided, of course, that this expected value exists). One can go on to define more general classes of random variables by taking suitable limits (for details, see [Younce, 1987]).

In classical probability theory (and especially in classical statistics) one usually focuses, not on the set of all possible probability weights, but on some designated subset of these (e.g., those belonging to a given family of distributions). Accordingly, by a *probabilistic model*, I mean pair $(\mathcal{A},\Delta)$ consisting of a test space $\mathcal{A}$ and a designated set of states $\Delta \subseteq \Omega(\mathcal{A})$ on $\mathcal{A}$. I’ll refer to $\mathcal{A}$ as the *test space* and to Δ as the *state space* of the model.

I’ll now indicate how this framework can accommodate both the usual measure-theoretic formalism of full-blown classical probability theory and the Hilbert-space formalism of quantum probability theory.

Kolmogorovian Probability Theory

Let S be a set, construed for the moment as the state-space of a physical system, and let Σ be a sigma-field of subsets of S. We can regard each partition E of S into countably many pair-wise disjoint Σ-measurable subsets as representing a 'coarse-grained' approximation to an imagined perfect experiment that would reveal the state of the system. Let $\mathcal{A}$ be the test space consisting of all such partitions. Note that the outcome set for $\mathcal{A}$ is the set $X = B - \{\varnothing\}$ of non-empty Σ-measurable subsets of S. Evidently, the probability weights on $\mathcal{A}$ correspond exactly to the countably additive probability measures on Σ.

Quantum Probability Theory

Let **H** denote a complex Hilbert space and let $\mathcal{A}$ denote the collection of (unordered) orthonormal bases of **H**. Thus, the outcome-space X of $\bigcup\mathcal{A}$ will be the unit sphere of **H**. Note that if u is any unit vector of **H** and $E \in \mathcal{A}$ is any orthonormal basis, we have

$$\sum_{x \in E} |\langle u,x\rangle|^2 = \|u\|^2 = 1$$

Thus, each unit vector of **H** determines a probability weight on $\mathcal{A}$. Quantum mechanics asks us to take this literally: any 'maximal' discrete quantum-mechanical observable is modeled by an orthonormal basis, and any pure quantum mechanical state, by a unit vector in exactly this way. Conversely, every orthonormal basis and every unit vector are understood to correspond to such a measurement and such a state.

Gleason's theorem can now be invoked to identify the states on $\mathcal{A}$ with the density operators on **H**: to each state ω in $\Omega(\mathcal{A}_{\mathbf{H}})$ there corresponds a unique density operator W such that, for every unit vector x of **H**, $\omega(x) = \langle Wx,x\rangle = Tr(WP_x)$, P_x being the one-dimensional projection associated with x. Conversely, of course, every such density operator defines a unique state by the formula above. We can also represent simple real-valued random variables operator-theoretically. Each bounded simple random variable f gives rise to a bounded self-adjoint operator $A = \Sigma_{x \in E} f(x)P_x$. The spectral theorem tells us that every self-adjoint operator on **H** can be obtained by taking suitable limits of operators of this form.

4. Logics associated with probabilistic models

Associated with any statistical model $(\mathcal{A},\Delta)$ are several partially ordered sets, each of which has some claim to the status of an 'empirical logic' associated with the model. In this section, I'll discuss two: the so-called *operational logic* $\Pi(\mathcal{A})$ and the *property lattice* $\mathbf{L}(\mathcal{A},\Delta)$. Under relatively benign conditions on $\mathcal{A}$, the former is an *orthoalgebra*. The latter is always a complete lattice, and under plausible further assumptions, atomic. Moreover, there is a natural order preserving mapping from Π to $\mathbf{L}$. This is not generally an order-isomorphism, but when it is, we obtain a complete orthomodular lattice, and thus come a step closer to the projection lattice of a Hilbert space.

Operational Logics

If $\mathcal{A}$ is a test space, an $\mathcal{A}$-*event* is a set of $\mathcal{A}$-outcomes that is contained in some test. In other words, an $\mathcal{A}$-event is simply an event in the classical sense for any one of the tests comprising $\mathcal{A}$. Now, if A and B are two $\mathcal{A}$-events, we say that A and B are *orthogonal*, and write $A \perp B$, if they are disjoint and their union is again an event. We say that two orthogonal events are *complements* of one another if their union is a test. We say that events A and B are *perspective*, and write $A \sim B$, if they share any common complement. (Notice that any two tests E and F are perspective, since they are both complementary to the empty event.)

> **4.1 Definition**:
> A test space $\mathcal{A}$ is said to be *algebraic* if for all events A, B, C of $\mathcal{A}$, $A \sim B$ and $B \perp C$ implies $A \perp C$.

While it is possible to construct perfectly plausible examples of test spaces that are not algebraic, most of test spaces that one encounters 'in nature' -- including the Borel and quantum test spaces described in the preceding section -- do seem to enjoy this property. The more important point is that, as an axiom, algebraicity is relatively benign, in the sense that many test spaces can be 'completed' to become algebraic. In particular, if every outcome has probability greater than .5 in at least one state, then $\mathcal{A}$ is contained in an algebraic test space $\mathcal{B}$ having the same outcomes and the same states as $\mathcal{A}$. (See [Gudder, 1985] for details).

Suppose now that $\mathcal{A}$ is algebraic. It is easy to see that the relation ~ of perspectivity is then an equivalence relation on the set of $\mathcal{A}$-events. More than this, if $\mathcal{A}$ is algebraic, then ~ is a *congruence* for the partial binary operation of forming unions of orthogonal events: in other words, $A \sim B$ and $B \perp C$ imply that $A \cup C \sim B \cup C$ for all $\mathcal{A}$-events A, B, and C.

Let $\Pi(\mathcal{A})$ be the set of equivalence classes of $\mathcal{A}$-events under perspectivity, and denote the equivalence class of an event A by $p(A)$; we then have a natural partial binary operation on $\Pi(\mathcal{A})$ defined by $p(A) \oplus p(B) = p(A \cup B)$ for orthogonal events A and B. Setting $0 := p(\varnothing)$ and $1 := p(E)$, E any member of $\mathcal{A}$, we obtain a partial-algebraic structure $(\Pi(\mathcal{A}), \oplus, 0, 1)$, called the *logic* of $\mathcal{A}$. This satisfies the following conditions:

a. $\oplus$ is associative and commutative:
   - If $a \oplus (b \oplus c)$ is defined, so is $(a \oplus b) \oplus c$, and the two are equal
   - If $a \oplus b$ is defined, so is $b \oplus a$, and the two are equal.

b. $0 \oplus a = a$, for every $a \in \mathbf{L}$

c. For every $a \in \mathbf{L}$, there exists a unique $a' \in \mathbf{L}$ with $a \oplus a' = 1$

d. $a \oplus a$ exists only if $a = 0$

We may now define:

4.2 Definition:
A structure (**L**,$\oplus$,0,1) satisfying conditions (a)-(d) above is called an *orthoalgebra*.

Thus, the logic of an algebraic test space is an orthoalgebra. One can show that, conversely, every orthoalgebra arises as the logic $\Pi(\mathcal{A})$ of an algebraic test space $\mathcal{A}$ (Golfin [1988]). Note that non-isomorphic test spaces can have isomorphic logics.

Orthocoherence

Any orthoalgebra **L** is partially ordered by the relation $a \leq b$ iff $b = a \oplus c$ for some $c \perp a$. Relative to this ordering, the mapping $a \rightarrow a'$ is an orthocomplementation and $a \perp b$ iff $a \leq b'$. It can be shown that $a \oplus b$ is always a minimal upper bound for *a* and *b*, but it is generally not the *least* upper bound. Indeed, we have the following [ref]:

4.3 Lemma:
For an orthoalgebra (**L**,$\oplus$,0,1), the following are equivalent:

a. $a \oplus b = a \vee b$, for all *a*, *b* in **L**
b. If $a \oplus b$, $b \oplus c$, and $c \oplus a$ all exist, then so does $a \oplus b \oplus c$
c. The orthoposet (**L**,$\leq$,$'$) is *orthomodular*, i.e., for all *a*, $b \in L$, if $a \leq b$ then $(b \wedge a') \vee a$ exists and equals *b*.

An orthoalgebra satisfying condition (b) is said to be *orthocoherent*. In other words: an orthoalgebra is ortho-coherent if and only if finite pair-wise summable subsets of **L** are jointly summable. The lemma tells us that every orthocoherent orthoalgebra is, *inter alia*, an orthomodular poset. Conversely, an orthocomplemented poset is orthomodular iff $a \oplus b = a \vee b$ is defined for all pairs with $a \leq b'$ and the resulting partial binary operation is associative -- in which case the resulting structure (**L**,$\oplus$,0,1) is an orthocoherent orthoalgebra, the canonical ordering on which agrees with the given ordering on **L**. Thus, orthomodular posets (the framework for Mackey's version of quantum logic) are equivalent to orthocoherent orthoalgebras.

Some version of orthocoherence was taken by Mackey and many of his successors as an axiom. (It appears, in an infinitary form, as Mackey's axiom V; a related but stronger condition appears in the definition of a partial Boolean algebra in the work of Kochen and Specker [1965].) However, it is quite easy to construct simple model test spaces, having perfectly straightforward -- even classical -- interpretations, the logics of which are not orthocoherent. As far as I know, there has never been given any entirely compelling reason for regarding orthocoherence as an essential feature of all reasonable physical models. Moreover, certain apparently quite well-motivated constructions that one wants to perform with test spaces tend to destroy orthocoherence (see Section 7).

Lattices of Properties

The decision to accept measurements and their outcomes as primitive concepts in our description of physical systems does not mean that we must forgo talk of the physical properties of such a system. Indeed, such talk is readily accommodated in our present formalism.[10] In the approach we have been pursuing, a physical system is represented by a probabilistic model $(\mathcal{A},\Delta)$, and the system's states are identified with the probability weights in Δ. Classically, *any* subset Γ of the state-space Δ corresponds to a categorical property of the system. However, in quantum mechanics, and indeed even classically, not every such property will be testable (or "physical"). (In quantum mechanics, only subsets of the state-space corresponding to closed subspaces of the Hilbert space are testable; in classical mechanics, one usually takes only, e.g., Borel sets to correspond to testable properties: the difference is that the testable properties in the latter case happen still to form a Boolean algebra of sets, where in the former case, they do not.)

One way to frame this distinction is as follows. The *support* of a set of states $\Gamma \subseteq \Delta$ is the set

$$S(\Gamma) = \{x \in X \mid \exists \omega \in \Gamma(\omega(x) > 0)\}$$

of outcomes that are possible when the property Γ obtains. There is a sense in which two properties are empirically indistinguishable if they have the same support: we cannot distinguish between them by means of a single execution of a single test. We might therefore wish to identify physical properties with classes of physically indistinguishable classical properties, or, equivalently, with their associated supports. However, if we wish to adhere to the programme of representing physical properties as subsets (rather than as equivalence-classes of subsets) of the state-space, we can do so, as follows. Define a mapping $F : \mathcal{P}(X) \to \mathcal{P}(\Delta)$ by $F(J) = \{\omega \in \Delta \mid S(\omega) \subseteq J\}$. The mapping $\Gamma \to F(S(\Gamma))$ is then a *closure operator* on $\mathcal{P}(\Delta)$, and the collection of closed sets (that is, the range of F) is a complete lattice of sets, closed under arbitrary intersection.[11] Evidently, classical properties -- subsets of Δ -- have the same support iff they have the same closure, so we may identify physical properties with closed subsets of the state-space:

> **4.4 Definition**:
> The *property lattice* of the model $(\mathcal{A},\Delta)$ is the complete lattice $\mathbf{L} = \mathbf{L}(\mathcal{A},\Delta)$ of all subsets of Δ of the form $F(J)$, J any set of outcomes. .[12]

We now have two different 'logics' associated with an entity $(\mathcal{A},\Delta)$ with $\mathcal{A}$ algebraic: a 'logic' $\Pi(\mathcal{A})$ of experimental propositions that is an orthoalgebra, but generally not a lattice, and a 'logic' $\mathbf{L}(\mathcal{A},\Delta)$ of properties that is a complete lattice, but rarely orthocomplemented in any natural way (Randall and Foulis, 1983). The two are connected by a natural mapping $[\ ] : \Pi \to \mathbf{L}$, given by $p \to [p] = F(J_p)$ where for each $p \in \Pi$, $J_p = \{x \in X \mid p(x) \nleq p'\}$. That is, J_p is the set of outcomes that are consistent with p, and $[p]$ is the largest (i.e., weakest) physical property making p certain to be confirmed if tested.

The mapping $p \to [p]$ is order preserving. For both the classical and quantum-mechanical models

considered above, it is in fact an order-isomorphism. Note that whenever this is the case, Π will inherit from **L** the structure of a complete lattice, which will then automatically be orthomodular by Lemma 4.3. In other words, in such cases we have only *one* logic, which is a complete orthomodular lattice. While it is surely too much to expect that every *conceivable* physical system should enjoy this property -- indeed, we can easily construct toy examples to the contrary -- the condition is at least reasonably transparent in its meaning.

5. Piron's Theorem

Suppose that the logic and property lattices of a model *are* isomorphic, so that the logic of propositions/properties is a complete orthomodular lattice. The question then arises: how close does this bring us to quantum mechanics – that is, to the projection lattice $L(\mathbf{H})$ of a Hilbert space?

The answer is: without additional assumptions, not very. The lattice $L(\mathbf{H})$ has several quite special order-theoretic features. First it is *atomic* -- every element is the join of minimal non-zero elements (i.e., one-dimensional subspaces). Second, it is *irreducible* -- it can not be expressed as a non-trivial direct product of simpler OMLs.[13] Finally, and most significantly, it satisfies the so-called *atomic covering law*: if $p \in L(\mathbf{H})$ is an atom and $p \not\leq q$, then $p \vee q$ *covers* q (no element of $L(\mathbf{H})$ lies strictly between $p \vee q$ and q).

These properties do not quite suffice to capture $L(\mathbf{H})$, but they do get us into the right ballpark. Let **V** be any inner product space over an involutive division ring D. A subspace **M** of **V** is said to be ⊥-*closed* iff $\mathbf{M} = \mathbf{M}^{\perp\perp}$, where $\mathbf{M}^{\perp} = \{v \in \mathbf{V} \mid \forall m \in \mathbf{M}(\langle v,m \rangle = 0)\}$. Ordered by set-inclusion, the collection $L(\mathbf{V})$ of all ⊥-closed subspaces of **V** forms a complete atomic lattice, orthocomplemented by the mapping $\mathbf{M} \rightarrow \mathbf{M}^{\perp}$. A theorem of Amemiya and Araki [1965] shows that a real, complex or quaternionic inner product space **V** with $L(\mathbf{V})$ orthomodular, is necessarily complete. For this reason, an inner product space **V** over an involutive division ring is called a *generalized Hilbert space* if its lattice of closed subspaces $L(\mathbf{V})$ is orthomodular. The following representation theorem is due to C. Piron [1964]:

> **5.1 Theorem**:
> Let L be a complete, atomic, irreducible orthomodular lattice satisfying the atomic covering law. If L contains at least 4 orthogonal atoms, then there exists an involutive division ring D and an inner-product space **V** over D such that L is isomorphic to $L(\mathbf{V})$.

It should be noted that generalized Hilbert spaces have been constructed over fairly exotic division rings.[14] Thus, while it brings us tantalizingly close, Piron's theorem does not quite bring us all the way back to orthodox quantum mechanics.

Conditioning and the Covering Law

Let us call a complete orthomodular lattice satisfying the hypotheses of Piron's theorem a *Piron lattice*. Can we give any general reason for supposing that the logic/property lattice of a physical system (one for

which these are isomorphic) is a Piron lattice? Or, failing this, can we at least ascribe some clear physical content to these assumptions? The atomicity of L follows if we assume that every pure state represents a "physical property". This is a strong assumption, but its content seems clear enough. Irreducibility is usually regarded as a benign assumption, in that a reducible system can be decomposed into its irreducible parts, to each of which Piron's Theorem applies.

The covering law presents a more delicate problem. While it is probably safe to say that no simple and entirely compelling argument has been given for assuming its general validity, Piron [1964, 1976] and others (e.g., Beltrametti and Cassinelli [1981] and Guz [1980]) have derived the covering law from assumptions about the way in which measurement results warrant inference from an initial state to a final state. Here is a brief sketch of how this argument goes. Suppose that there is some reasonable way to define, for an initial state q of the system, represented by an atom of the logic/property lattice L, a final state $\varphi_p(q)$ -- either another atom, or perhaps 0 -- conditional on the proposition p having been confirmed. Various arguments can be adduced suggesting that the only reasonable candidate for such a mapping is the *Sasaki projection* $\varphi_p : L \rightarrow L$, defined by $\varphi_p(q) = (q \vee p') \wedge p$.[15] It can be shown that an atomic OML satisfies the atomic covering law just in case Sasaki projections take atoms again to atoms, or to 0. Another interesting view of the covering law is developed by Cohen and Svetlichny [1987].

6. Classical Representations

The perennial question in the interpretation of quantum mechanics is that of whether or not essentially classical explanations are available, even in principle, for quantum-mechanical phenomena. Quantum logic has played a large role in shaping (and clarifying) this discussion, in particular by allowing us to be quite precise about what we *mean* by a classical explanation.

Classical Embeddings

Suppose we are given a statistical model $(\mathcal{A}, \Delta)$. A very straightforward approach to constructing a "classical interpretation" of $(\mathcal{A}, \Delta)$ would begin by trying to embed $\mathcal{A}$ in a Borel test space $\mathcal{B}$, with the hope of then accounting for the statistical states in Δ as averages over "hidden" classical -- that is, dispersion-free -- states on the latter. Thus, we'd want to find a set S and a mapping $X \rightarrow \mathcal{P}(S)$ assigning to each outcome x of $\mathcal{A}$ a *set* $x^* \subseteq S$ in such a way that, for each test $E \in \mathcal{A}$, $\{x^* \mid x \in E\}$ forms a partition of S. If this can be done, then each outcome x of $\mathcal{A}$ simply records the fact that the system is in one of a certain set of states, namely, x^*. If we let Σ be the Σ-algebra of sets generated by sets of the form $\{x^* \mid x \in X\}$, we find that each probability measure μ on Σ pulls back to a state μ^* on $\mathcal{A}$, namely, $\mu^*(x) = \mu(x^*)$. So long as every state in Δ is of this form, we may claim to have given a completely classical interpretation of the model $(\mathcal{A}, \Delta)$.

The minimal candidate for S is the set of *all* dispersion-free states on $\mathcal{A}$. Setting $x^* = \{s \in S \mid s(x) = 1\}$ gives us a classical interpretation as above, which I'll call the *classical image* of $\mathcal{A}$. Any other classical

interpretation factors through this one. Notice, however, that the mapping $x \to x^*$ is injective only if there are sufficiently many dispersion-free states to separate distinct outcomes of $\mathcal{A}$. If $\mathcal{A}$ has *no* dispersion-free states at all, then its classical image is *empty*. Gleason's theorem tells us that this is the case for quantum-mechanical models. Thus, this particular kind of classical explanation is not available for quantum mechanical models.

It is sometimes overlooked that, even if a test space $\mathcal{A}$ does have a separating set of dispersion-free states, there may exist statistical states on $\mathcal{A}$ that *can not* be realized as mixtures of these. The classical image provides no explanation for such states. For a very simple example of this sort of thing, consider the the test space:

$$\mathcal{A} = \{\{a, x, b\}, \{b, y, c\}, \{c, z, a\}\}$$

and the state $\omega(a) = \omega(b) = \omega(c) = ½$, $\omega(x) = \omega(y) = \omega(z) = 0$. It is a simple exercise to show that ω cannot be expressed as a weighted average of {0,1}-valued states on $\mathcal{A}$. For further examples and discussion of this point, see Wright [1980].]

Contextual Hidden Variables

The upshot of the foregoing discussion is that most test spaces can't be embedded into any classical test space, and that even where such an embedding exists, it typically fails to account for some of the model's states. However, there is one very important class of models for which a satisfactory classical interpretation is *always* possible. Let us call a test space $\mathcal{A}$ *semi-classical* if its tests do not overlap; i.e., if $E \cap F = \emptyset$ for $E, F \in \mathcal{A}$, with $E \neq$ F.

6.1 Lemma:
Let $\mathcal{A}$ be semi-classical. Then $\mathcal{A}$ has a separating set of dispersion-free states, and every extreme state on $\mathcal{A}$ is dispersion-free.

As long as $\mathcal{A}$ is locally countable (i.e., no test E in $\mathcal{A}$ is uncountable), every state can be represented as a convex combination, in a suitable sense, of extreme states [Wilce, 1992]. Thus, every state of a locally countable semi-classical test space has a classical interpretation.

Even though neither Borel test spaces nor quantum test spaces are semi-classical, one might argue that in any real laboratory situation, semi-classicality is the rule. Ordinarily, when one writes down in one's laboratory notebook that one has performed a given test and obtained a given outcome, one always has a record of which test was performed. Indeed, given any test space $\mathcal{A}$, we may always form a semi-classical test space simply by forming the co-product (disjoint union) of the tests in $\mathcal{A}$. More formally:

6.2 Definition:
For each test E in $\mathcal{A}$, let $E^{\sim} = \{ (x,E) \mid x \in E \}$. The *semi-classical cover* of $\mathcal{A}$ is the test space

$$\mathcal{A}^{\sim} = \{E^{\sim} \mid E \in \mathcal{A}\}.$$

We can regard $\mathcal{A}$ as arising from $\mathcal{A}^{\sim}$ by deletion of the record of which test was performed to secure a given outcome. Note that every state on $\mathcal{A}$ defines a state $\tilde{\omega}$ on $\mathcal{A}^{\sim}$ by $\tilde{\omega}(x,E) = \omega(x)$. The mapping $\omega \to \tilde{\omega}$ is plainly injective; thus, we may identify the state-space of $\mathcal{A}$ with a subset of the state-space of $\mathcal{A}^{\sim}$. Notice that there will typically be many states on $\mathcal{A}^{\sim}$ that *do not* descend to states on $\mathcal{A}$. We might wish to think of these as "non-physical", since they do not respect the (presumably, physically motivated) outcome-identifications whereby $\mathcal{A}$ is defined.

Since it is semi-classical, $\mathcal{A}^{\sim}$ admits a classical interpretation, as per Lemma 7.1. Let's examine this. An element of $S(\mathcal{A}^{\sim})$ amounts to a mapping $f : \mathcal{A}^{\sim} \to X$, assigning to each test $E \in \mathcal{A}$, an outcome $f(E) \in E$. This is a (rather brutal) example of what is meant by a *contextual (dispersion-free) hidden variable*. The construction above tells us that such contextual hidden variables will be available for statistical models quite generally. For other results to the same effect, see Kochen and Specker [1967], Gudder [1970], Holevo [1982], and, in a different direction, Pitowsky [1989].[16]

Note that the simple random variables on $\mathcal{A}$ correspond exactly to the simple random variables on $\mathcal{A}^{\sim}$, and that these, in turn, correspond to *some* of the simple random variables (in the usual sense) on the measurable space $S(\mathcal{A}^{\sim})$. Thus, we have the following picture: The model $(\mathcal{A},\Delta)$ can always be obtained from a classical model simply by omitting some random variables, and identifying outcomes that can no longer be distinguished by those that remain.

All of this might suggest that our generalized probability theory presents no significant conceptual departure from classical probability theory. On the other hand, models constructed along the foregoing lines have a distinctly ad hoc character. In particular, the set of "physical" states in one of the classical (or semi-classical) models constructed above is determined not by any independent physical principle, but only by consistency with the original, non-semiclassical model. Another objection is that the contextual hidden variables introduced in this section are badly non-local. It is by now widely recognized that this non-locality is the principal locus of non-classicality in quantum (and more general) probability models. (For more on this, see the entry on the Bell inequalities.)

7. Composite Systems

Some of the most puzzling features of quantum mechanics arise in connection with attempts to describe compound physical systems. It is in this context, for instance, that both the measurement problem and the non-locality results centered on Bell's theorem arise. It is interesting that coupled systems also present a challenge to the quantum-logical programme. I will conclude this article with a description of two results that show that the coupling of quantum-logical models tends to move us further from the realm of Hilbert space quantum mechanics.

The Foulis-Randall Example

A particularly striking result in this connection is the observation of Foulis and Randall [1981] that any reasonable (and reasonably general) tensor product of orthoalgebras will fail to preserve ortho-coherence. Let $\mathcal{A}_5$ denote the test space

$$\{\{a,x,b\}, \{b,y,c\}, \{c,z,d\}, \{d,w,e\}, \{e,v,s\}\}$$

consisting of five three-outcome tests pasted together in a loop. This test space is by no means pathological; it is both ortho-coherent and algebraic. Moreover, it admits a separating set of dispersion-free states and hence, a classical interpretation. Now consider how we might model a compound system consisting of two separated sub-systems each modeled by $\mathcal{A}_5$. We would need to construct a test space $\mathcal{B}$ and a mapping $\otimes : X \times X \to Y = \cup\mathcal{B}$ satisfying, minimally, the following;

a. For all outcomes $x, y, z \in X$, if $x \perp y$, then $x \otimes z \perp y \otimes z$ and $z \otimes x \perp z \otimes y$,
b. For each pair of states $\alpha, \beta \in \Omega(\mathcal{A}_5)$, there exists at least one state ω on $\mathcal{B}$ such that $\omega(x \otimes y) = \alpha(x)\beta(y)$, for all outcomes $x, y \in X$.

Foulis and Randall show that no such embedding exists for which $\mathcal{B}$ is orthocoherent.

Aerts' Theorem

Another result having a somewhat similar force is that of Aerts [1982]. If L_1 and L_2 are two Piron lattices, Aerts constructs in a rather natural way a lattice L representing two *separated* systems, each modeled by one of the given lattices. Here "separated" means that each pure state of the larger system L is entirely determined by the states of the two component systems L_1 and L_2. Aerts then shows that L is again a Piron lattice iff at least one of the two factors L_1 and L_2 is classical. (This result has recently been strengthened by Ischi [2000] in several ways.)

The thrust of these no-go results is that straightforward constructions of plausible models for composite systems destroy regularity conditions (ortho-coherence in the case of the Foulis-Randall result, orthomodularity and the covering law in that of Aerts' result) that have widely been used to underwrite reconstructions of the usual quantum-mechanical formalism. This puts in doubt whether any of these conditions can be regarded as having the universality that the most optimistic version of Mackey's programme asks for. Of course, this does not rule out the possibility that these conditions may yet be motivated in the case of especially *simple* physical systems.

The Basic Theory of Ordering Relations

What follows is the briefest possible summary of the order-theoretic notions used in the main text. For a good introduction to this material, see Davey & Priestley [1990]. More advanced treatments can be found in Gratzer [1998] and Birkhoff [1967].

---

1. Ordered Sets

A *partial ordering* -- henceforth, just an ordering -- on a set P is a reflexive, anti-symmetric, and transitive binary relation $\trianglelefteq$ on P. Thus, for all p, q, $r \in P$, we have

1. $p \trianglelefteq p$
2. $p \trianglelefteq q$ and $q \trianglelefteq p$ only if $p = q$.
3. if $p \trianglelefteq q$ and $q \trianglelefteq r$ then $p \trianglelefteq r$

If $p \trianglelefteq q$, we speak of p as being *less than*, or *below* q, and of q as being *greater than*, or *above* p, in the ordering.

A *partially ordered set*, or *poset*, is a pair $(P, \trianglelefteq)$ where P is a set and $\trianglelefteq$ is a specified ordering on P. It is usual to let P denote both the set and the structure, leaving $\trianglelefteq$ tacit wherever possible. Any collection of subsets of some fixed set X, ordered by set-inclusion, is a poset; in particular, the full power set $\mathcal{P}(X)$ is a poset under set inclusion.

Let P be a poset. The *meet*, or *greatest lower bound*, of p, $q \in P$, denoted by $p \wedge q$, is the greatest element of P -- if there is one -- lying below both p and q. The *join*, or *least upper bound*, of p and q, denoted by $p \vee q$, is the least element of P -- if there is one -- lying above both p and q. Thus, for any elements p, q, r of P, we have

a. if $r \trianglelefteq p \wedge q$, then $r \trianglelefteq p$ and $r \trianglelefteq q$
b. if $p \vee q \trianglelefteq r$, then $p \trianglelefteq r$ and $q \trianglelefteq r$

Note that $p \wedge p = p \vee p = p$ for all p in P. Note also that $p \trianglelefteq q$ iff $p \wedge q = p$ iff $p \vee q = q$.

Note that if the set $P = \mathcal{P}(X)$, ordered by set-inclusion, then $p \wedge q = p \cap q$ and $p \vee q = p \cup q$. However, if P is an arbitrary collection of subsets of X ordered by inclusion, this need not be true. For instance, consider the collection P of all subsets of $X = \{1,2,...,n\}$ having even cardinality. Then, for instance, $\{1,2\} \vee \{2,3\}$ does not exist in P, since there is no *smallest* set of 4 elements of X containing $\{1,2,3\}$. For a different sort of example, let X be a vector space and let P be the set of *subspaces* of X. For subspaces **M** and **N**, we have

$$\mathbf{M} \wedge \mathbf{N} = \mathbf{M} \cap \mathbf{N}, \text{ but } \mathbf{M} \vee \mathbf{N} = \text{span}(\mathbf{M} \cup \mathbf{N}).$$

The concepts of meet and join extend to infinite subsets of a poset P. Thus, if $A \subseteq P$, the meet of A is the largest element (if any) below A, while the join of A is the least element (if any) above A. We denote the meet of A by $\wedge A$ or by $\wedge_{a \in A}\, a$. Similarly, the join of A is denoted by $\vee A$ or by $\vee_{a \in A}\, a$.

2. Lattices

A *lattice* is a poset $(L, \trianglelefteq)$ in which every pair of elements has both a meet and a join. A *complete lattice* is one in which *every* subset of L has a meet and a join. Note that $\mathcal{P}(X)$ is a complete lattice with respect to set inclusion, as is the set of all subspaces of a vector space. The set of finite subsets of an infinite set X is a lattice, but not a complete lattice. The set of subsets of a finite set having an even number of elements is an example of a poset that is not a lattice.

A lattice $(L, \trianglelefteq)$ is *distributive* iff meets distribute over joins and vice versa:

$$p \wedge (q \vee r) = (p \wedge q) \vee (p \wedge r), \text{ and}$$

$$p \vee (q \wedge r) = (p \vee q) \wedge (p \vee r).$$

The power set lattice $\mathcal{P}(X)$, for instance, is distributive (as is any lattice of sets in which meet and join are given by set-theoretic intersection and union). On the other hand, the lattice of subspaces of a vector space is not distributive, for reasons that will become clear in a moment.

A lattice L is said to be bounded iff it contains a smallest element 0 and a largest element 1. Note that any complete lattice is automatically bounded. For the balance of this appendix, *all lattices are assumed to be bounded*, absent any indication to the contrary.

A *complement* for an element p of a (bounded) lattice L is another element q such that $p \wedge q = 0$ and $p \vee q = 1$.

In the lattice $\mathcal{P}(X)$, every element has exactly one complement, namely, its usual set-theoretic complement. On the other hand, in the lattice of subspaces of a vector space, an element will typically have infinitely many complements. For instance, if L is the lattice of subspaces of 3-dimensional Euclidean space, then a complement for a given plane through the origin is provided by any line through the origin not lying in that plane.

> **Proposition**:
> If L is distributive, an element of L can have at most one complement.
>
> **Proof**:
> Suppose that q and r both serve as complements for p. Then, since L is distributive, we have
>
> $$\begin{aligned} q &= q \wedge 1 \\ &= q \wedge (p \vee r) \\ &= (q \wedge p) \vee (q \wedge r) \\ &= 0 \vee (q \wedge r) \\ &= q \wedge r \end{aligned}$$
>
> Hence, $q \trianglelefteq r$. Symmetrically, we have $r \trianglelefteq q$; thus, $q = r$.

Thus, no lattice in which elements have multiple complements is distributive. In particular, the subspace lattice of a vector space (of dimension greater than 1) is not distributive.

If a lattice *is* distributive, it may be that some of its elements have a complement, while others lack a complement. A distributive lattice in which every element has a complement is called a *Boolean lattice* or a *Boolean algebra*. The basic example, of course, is the power set $\mathcal{P}(X)$ of a set X. More generally, any collection of subsets of X closed under unions, intersections and complements is a Boolean algebra; a theorem of Stone and Birkhoff tells us that, up to isomorphism, every Boolean algebra arises in this way.

3. Ortholattices

In some non-uniquely complemented (hence, non-distributive) lattices, it is possible to pick out, for each element p, a preferred complement p' in such a way that

a. if $p \trianglelefteq q$ then $q' \trianglelefteq p'$
b. $p'' = p$

When these conditions are satisfied, one calls the mapping $p \to p'$ an *orthocomplementation* on L, and the structure $(L, \trianglelefteq, ')$ an *orthocomplemented lattice*, or an *ortholattice* for short.

Note again that if a distributive lattice can be orthocomplemented at all, it is a Boolean algebra, and hence can be orthocomplemented in only one way. In the case of $L(\mathbf{H})$ the orthocomplementation one has in mind is $\mathbf{M} \to \mathbf{M}^{\perp}$ where $\mathbf{M}^{\perp}$ is defined as in Section 1 of the main text. More generally, if $\mathbf{V}$ is any inner product space (complete or not), let $L(\mathbf{V})$ denote the set of subspaces $\mathbf{M}$ of $\mathbf{V}$ such that $\mathbf{M} = \mathbf{M}^{\perp\perp}$ (such a subspace is said to be algebraically closed). This again is a complete lattice, orthocomplemented by the mapping $\mathbf{M} \to \mathbf{M}^{\perp}$.

4. Orthomodularity

There is a striking order-theoretic characterization of the lattice of closed subspaces of a Hilbert space among lattices $L(\mathbf{V})$ of closed subspaces of more general inner product spaces. An ortholattice L is said to be orthomodular iff, for any pair p, q in L with $p \trianglelefteq q$,

(OMI) $\quad (q \wedge p') \vee p = q.$

Note that this is a weakening of the distributive law. Hence, a Boolean lattice is orthomodular. It is not difficult to show that if $\mathbf{H}$ is a Hilbert space, then $L(\mathbf{H})$ is orthomodular. The striking converse of this fact is due to Amemiya and Araki [1965]:

> **Theorem**:
> Let $\mathbf{V}$ be an inner product space (over $\mathbf{R}$, $\mathbf{C}$ or the quaternions) such that $L(\mathbf{V})$ is orthomodular. Then $\mathbf{V}$ is complete, i.e., a Hilbert space.

5. Closure Operators, Interior Operators and Adjunctions

Let P and Q be posets. A mapping $f : P \to Q$ is *order preserving* iff for all $p,q \in P$, if $p \trianglelefteq q$ then $f(p) \trianglelefteq f(q)$.

A *closure operator* on a poset P is an order-preserving map $\mathbf{cl} : P \to P$ such that for all $p \in P$,

- $\mathbf{cl}(\mathbf{cl}(p)) = p$
- $p \trianglelefteq \mathbf{cl}(p)$.

Dually, an *interior operator* on P is an order-preserving mapping $\mathbf{int} : P \to P$ on P such that for all $p \in P$,

- $\mathbf{int}(\mathbf{int}(p)) = \mathbf{int}(p)$

- **int**(p) $\trianglelefteq$ p

Elements in the range of **cl** are said to be *closed*; those in the range of **int** are said to be *open*. If P is a (complete) lattice, then the set of closed, respectively open, subsets of P under a closure or interior mapping is again a (complete) lattice.

By way of illustration, suppose that $\mathcal{O}$ and $\mathcal{C}$ are collections of subsets of a set X with $\mathcal{O}$ closed under arbitrary unions and $\mathcal{C}$ under arbitrary intersections. For any set $A \subseteq X$, let

> **cl**(A) = $\bigcap\{C \in \mathcal{C} \mid A \subseteq C\}$, and
>
> **int**(A) = $\bigcup\{O \in \mathcal{O} \mid O \subseteq A\}$

Then **cl** and **int** are interior operators on $\mathcal{P}(X)$, for which the closed and open sets are precisely $\mathcal{C}$ and $\mathcal{O}$, respectively. The most familiar example, of course, is that in which $\mathcal{O}$, $\mathcal{C}$ are the open and closed subsets, respectively, of a topological space. Another important special case is that in which $\mathcal{C}$ is the set of linear subspaces of a vector space **V**; in this case, the mapping *span* : $\mathcal{P}$(**V**) $\rightarrow$ $\mathcal{P}$(**V**) sending each subset of **V** to its span is a corresponding closure.

An *adjunction* between two posets P and Q is an ordered pair (f, g) of mappings $f : P \rightarrow Q$ and $g : Q \rightarrow P$ connected by the condition that, for all $p \in P$, $q \in Q$

> $f(p) \trianglelefteq q$ if and only if $p \trianglelefteq g(q)$.

In this case, we call f a *left adjoint* for g, and call g a *right adjoint* for f. Two basic facts about adjunctions, both easily proved, are the following:

> **Proposition**:
> Let $f : L \rightarrow M$ be an order-preserving map between complete lattices L and M. Then
>
> a. f preserves arbitrary joins if and only if it has a right adjoint.
> b. f preserves arbitrary meets if and only if it has a left adjoint.

> **Proposition**:
> Let (f, g) be an adjunction between complete lattices L and M. Then
>
> a. $g \circ f : L \rightarrow L$ is a closure operator.
> b. $f \circ g : M \rightarrow M$ is an interior operator.

Stanford Encyclopedia of Philosophy
Notes to Quantum Logic and Quantum Probability

Notes

1. A few qualifications are in order already: In a more general formulation, one considers the lattice of projections of a von Neumann algebra. Only in the context of non-relativistic quantum mechanics, and then only absent superselection rules, is this algebra a type I factor. For the expository purposes of this paper, we restrict our discussion to this context.

2. Throughout this paper, I use the term "logic" rather narrowly to refer to the algebraic and order-theoretic aspect of propositional logic. There exists a substantial technical literature devoted to non-classical formal deductive systems that are intended to stand to quantum propositional logics rather as classical deductive systems stand to Boolean algebras. A good reference for this material is Kalmbach [1983].

3. It is important to note here that even in classical mechanics, only subsets of the state-space that are measurable (in the sense of measure theory) are regarded as representing observable properties of the system, and only these are assigned probabilities. The difference is that in the classical case, the observable properties form a sub-Boolean algebra of the power set of *S*, while in the quantum case, they do not.

4. The first explicit formulation of this interpretation seems to have been given by Jauch and Piron [1969].

5. So-called *modal* interpretations of quantum mechanics do not attempt to assign actual values (or ranges of values) to *all* observables. Rather, they identify (in various different ways) a privileged observable or class of observables as having "definite values", and thereby avoid the various no-go theorems for hidden variables. For references and further details, see the entry on modal interpretations of Quantum Mechanics.

6. Of course, another possible response to such a question is to dismiss it, perhaps with the observation that mathematical models of natural phenomena evolve, more or less organically, to fit the facts, and require no a priori justification. Or, to put it differently, we can insist that quantum logic has the structure that it does just because the *world* has that structure.

7. These include, besides Mackey's original formalism, that of Piron [1976], the approach based on partial Boolean algebras of Kochen and Specker [1965, 1967], and various approaches emphasizing the

convex structure of the set of (statistical) states of a system, e.g., [Holevo 1982, Ludwig 1983, Pitowsky 1989].

8. Even at this point, a couple of remarks are in order. First, notice that *E* need not be the set of outcomes of any humanly executable, let alone repeatable, measurement or experiment. Any exhaustive set of mutually exclusive alternatives will serve, at least as long as some sense can be attached to the terms “occurrence” and "realization" (even as terms of art). Secondly, notice that every standard interpretation of probability theory, whether relative-frequentist, propensity, subjective or what-have-you, represents probability weights mathematically in the same way. Thus, the framework just sketched is agnostic among these interpretations.

9. It is worth remarking that all approaches to a generalized probability theory contain some mechanism for identifying outcomes of distinct measurements or values of distinct observables, though this mechanism varies from author to author . The most common approaches are to identify outcomes that are equi-probable in every state (as in the work of Mackey), or to identify outcomes that are certain (i.e., have probability 1) in exactly the same states (as in the work of Piron). Both of these prescriptions become problematic in the context of sequential measurements --- see, e.g., [Cooke and Hilgevoord, 1979]. The Foulis-Randall theory has the advantage of remaining neutral as to the precise mechanism whereby outcomes are identified.

10. The approach taken here is modeled on, but somewhat less general than, that of Foulis, Piron and Randall [1983]. See also [Foulis and Randall, 1987]

11. Indeed, the pair (S, F) is an *adjunction* between $\mathcal{P}(X)$ and $\mathcal{P}(\Delta)$ -- that is, for any $\Gamma \in \mathcal{P}(\Delta)$ and any $J \in \mathcal{P}(X)$, we have $S(\Gamma) \subseteq J$ if and only if $\Gamma \subseteq F(J)$. It follows that the mappings

$$\Gamma \rightarrow F(S(\Gamma)) \text{ and } J \rightarrow S(F(J))$$

are respectively a closure operator on $\mathcal{P}(\Delta)$ and an interior operator on $\mathcal{P}(X)$. The collection of closed subsets of Δ and the collection of open subsets of X (which are exactly the ranges of the mappings F and S) are complete lattices, closed under intersection and union respectively, and are mapped isomorphically onto one another by S and F. (See Supplement 2 for further details.)

12. In the case where Δ is a *convex* set of states the closed subsets of Δ are *faces* of Δ; that is, $F(J)$ is itself convex, and if a convex combination of states lies in $F(J)$, then those states themselves lie in $F(J)$. The faces of any convex set Δ, ordered by inclusion, form a complete lattice, closed under intersection. Thus, in this context, the property lattice is a complete sublattice of the face lattice of the state-space. This is the starting point for a number of approaches to generalized probability theory. Note that if Δ is a simplex, as it is for classical models, then the face lattice of Δ is a Boolean algebra.

13. This condition fails for the projection lattice modeling a quantum-mechanical system with

superselection rules, but continues to hold for the lattices associated with each superselection sector.

14. The first such examples were obtained by H. Keller. Recently, M. P. Soler has shown that if a generalized Hilbert space contains any infinite orthonormal set, it must in fact be a classical Hilbert space --- i.e., the division ring D must be the field of real numbers, the field of complex numbers, or the ring of quaternions. See Holland [1995] for references and further discussion.

15. For a development of this idea in a more general context, see Wilce [2000].

16. Interesting recent work of Mayers [1999] and Clifton and Kent [2000] shows that the quantum test space *F*(**H**) contains a dense semi-classical sub-test space. A detailed hidden-variables model along these lines has not been seriously entertained (and would presumably be otherwise problematic), but these results do suggest that experiments having finite precision can not rule out non-contextual hidden variables.

Relational Quantum Mechanics

Relational quantum mechanics is an interpretation of quantum theory which discards the notions of absolute state of a system, absolute value of its physical quantities, or absolute event. The theory describes only the way systems affect each other in the course of physical interactions. State and physical quantities refer always to the interaction, or the relation, between *two* systems. Nevertheless, the theory is assumed to be complete. The physical content of quantum theory is understood as expressing the net of relations connecting all different physical systems.

1. Introduction

Quantum theory is our current general theory of physical motion. The theory is the core component of the momentous change that our understanding of the physical world has undergone during the first

decades of the 20th century. It is one of the most successful scientific theories ever: it is supported by vast and unquestionable empirical and technological effectiveness and is today virtually unchallenged. But the interpretation of what the theory actually tells us about the physical world raises a lively debate, which has continued with alternating fortunes, from the early days of the theory in the late twenties, to nowadays. The *relational interpretations* are a number of reflections by different authors, which were independently developed, but converge in indicating an interpretation of the physical content of the theory. The core idea is to read the theory as a theoretical account of the way distinct physical systems *affect each other* when they interact (and not of the way physical systems "are"), and the idea that this account exhausts all that can be said about the physical world. The physical world is thus seen as a net of interacting components, where there is no meaning to the state of an isolated system. A physical system (or, more precisely, its contingent state) is reduced to the net of relations it entertains with the surrounding systems, and the physical structure of the world is identified as this net of relationships.

The possibility that the physical content of an empirically successful physical theory could be debated should not surprise: examples abound in the history of science. For instance, the great scientific revolution was fueled by the grand debate on whether the effectiveness of the Copernican system could be taken as an indication that the Earth was not *in fact* at the center of the universe. In more recent times, Einstein's celebrated first major theoretical success, special relativity, consisted to a large extent just in understanding the physical meaning (simultaneity is relative) of an already existing effective mathematical formalism (the Lorentz transformations). In these cases, as in the case of quantum mechanics, a very strictly empiricist position could have circumvented the problem altogether, by reducing the content of the theory to a list of predicted numbers. But perhaps science can offer us more than such a list; and certainly science needs more than such a list to find its ways.

The difficulty in the interpretation of quantum mechanics derives from the fact that the theory was first constructed for describing microscopic systems (atoms, electrons, photons) and the way these interact with macroscopic apparatuses built to measure their properties. Such interactions are denoted as "measurements". The theory consists in a mathematical formalism, which allows probabilities of alternative outcomes of such measurements to be calculated. If used just for this purpose, the theory raises no difficulty. But we expect the macroscopic apparatuses themselves -- in fact, any physical system in the world -- to obey quantum theory, and this seems to raise contradictions in the theory.

1.1 The Problem

In classical mechanics, a system S is described by a certain number of physical variables. For instance, an electron is described by its position and its spin (intrinsic angular momentum). These variables change with time and represent the contingent properties of the system. We say that their values determine, at every moment, the "state" of the system. A measurement of a system's variable is an interaction between the system S and an external system O, whose effect on O, depends on the actual value q of the variable (of S) which is measured. The characteristic feature of quantum mechanics is that it does not allow us to assume that all variables of the system have determined values at every moment (this irrespectively of whether or not we know such values). It was Werner Heisenberg who first realized the need to free

ourselves from the belief that, say, an electron has a well determined position at every time. When it is not interacting with an external system that can detect its position, the electron can be "spread out" over different positions. In the jargon of the theory, one says that the electron is in a "quantum superposition" of two (or many) different positions. It follows that the state of the system cannot be captured by giving the value of its variables. Instead, quantum theory introduces a new notion of "state" of a system, which is different from a list of values of its variables. Such a new notion of state was developed in the work of Erwin Schrödinger in the form of the "wave function" of the system, usually denoted by Ψ. Paul Adrien Maurice Dirac gave a general abstract formulation of the notion of quantum state, in terms of a vector Ψ moving in an abstract vector space. The time evolution of the state Ψ is deterministic and is governed by the Schrödinger equation. From the knowledge of the state Ψ, one can compute the probability of the different measurement outcomes q. That is, the probability of the different ways in which the system S can affect a system O in an interaction with it. The theory then prescribes that at every such ‘measurement’, one must update the value of Ψ, to take into account which of the different outcomes has happened. This sudden change of the state Ψ depends on the specific outcome of the measurement and is therefore probabilistic. It is called the "collapse of the wave function".

The problem of the interpretation of quantum mechanics takes then different forms, depending on the relative ontological weight we choose to assign to the wave function Ψ or, respectively, to the sequence of the measurement outcomes q, q', q'', …. If we take Ψ as the "real" entity which fully represents the actual state of affairs of the world, we encounter a number of difficulties. First, we have to understand how Ψ can change suddenly in the course of a measurement: if we describe the evolution of two interacting quantum systems in terms of the Schrödinger equation, no collapse happens. Furthermore, the collapse, seen as a physical process, seems to depend on arbitrary choices in our description and shows a disturbing amount of nonlocality. But even if we can circumvent the collapse problem, the more serious difficulty of this point of view is that it appears to be impossible to understand how specific observed values q, q', q'', … can emerge from the same Ψ. A better alternative is to take the observed values q, q', q'', … as the actual elements of reality, and view Ψ just as a bookkeeping device, determined by the actual values q, q', q'', … that happened in past. From this perspective, the real events of the world are the "realization" (the "coming to reality", the "actualization") of the values q, q', q'', … in the course of the interaction between physical systems. This actualization of a variable q in the course of an interaction can be denoted as the *quantum event* q. An exemple of a quantum event is the detection of an electron in a certain position. The position variable of the electron assumes a determined value in the course of the interaction between the electron and an external system and the quantum event is the "manifestation" of the electron in a certain position. Quantum events have an intrinsically discrete ("quantized") granular structure.

The difficulty of this second option is that if we take the quantum nature of all physical systems into account, the statement that a certain specific event q "has happened" (or, equivalently that a certain variable has or has not taken the value q) can be true and not-true at the same time. To clarify this key point, consider the case in which a system S interacts with another system (an apparatus) O, and exhibits a value q of one of its variables. Assume that the system O obeys the laws of quantum theory as well, and use the quantum theory of the combined system formed by O and S in order to predict the way this combined system can later interact with a *third* system O'. Then quantum mechanics forbids us to

assume that q has happened. Indeed, as far as its later behavior is concerned, the combined system $S+O$ may very well be in a quantum superposition of alternative possible values q, q', q'', …. This "second observer" situation captures the core conceptual difficulty of the interpretation of quantum mechanics: reconciling the possibility of quantum superposition with the fact that the observed world is characterized by uniquely determined events q, q', q'', …. More precisely, it shows that we cannot disentangle the two: according to the theory an observed quantity (q) can be at the same time determined and not determined. An event may have happened and at the same time may not have happened.

2. Relational view of quantum states

The way out from this dilemma suggested by the relational interpretation is that the quantum events, and thus the values of the variables of a physical system S, namely the q's, are relational. That is, they do not express properties of the system S alone, but rather refer to the relation between two systems. In particular, the central tenet of *relational quantum mechanics* (Rovelli 1996, 1997) is that there is no meaning in saying that a certain quantum event has happened or that a variable of the system S has taken the value q: rather, there is meaning in saying that the event q has happened or the variable has taken the value *q for O*, or *with respect to O*. The apparent contradiction between the two statements that a variable has or hasn't a value is resolved by indexing the statements with the different systems with which the system in question interacts. If I observe an electron at a certain position, I cannot conclude that the electron *is* there: I can only conclude that the electron *as seen by me* is there. Quantum events only happen in interactions between systems, and the fact that a quantum event has happened is only true with respect to the systems involved in the interaction. The unique account of the state of the world of the classical theory is thus fractured into a multiplicity of accounts, one for each possible "observing" physical system. In the words of (Rovelli 1996): "Quantum mechanics is a theory about the physical description of physical systems relative to other systems, and this is a complete description of the world".

This relativisation of actuality is viable thanks to a remarkable property of the formalism of quantum mechanics. John von Neumann was the first to notice that the formalism of the theory treats the measured system (S) and the measuring system (O) differently, but the theory is surprisingly flexible on the choice of where to put the boundary between the two. Different choices give different accounts of the state of the world (for instance, the collapse of the wave function happens at different times); but this does not affect the predictions on the final observations. Von Neumann only described a rather special situation, but this flexibility reflects a general structural property of quantum theory, which guarantees the consistency among all the distinct "accounts of the world" of the different observing systems. The manner in which this consistency is realized, however, is subtle.

What appears with respect to O as a measurement of the variable q (with a specific outcome), appears with respect to O' simply as the establishing of a *correlation* between S and O (without any specific outcome). As far as the observer O is concerned, a quantum event has happened and a property q of a system S has taken a certain value. As far as the second observer O' is concerned, the only relevant element of reality is that a correlation is established between S and O. This correlation will manifest itself only in any further observation that O' would perform on the $S+O$ system. Up to the time in which it

physically interacts with $S+O$, the system O' has no access to the actual outcomes of the measurements performed by O on S . This actual outcome is real only with respect to O (Rovelli 1996, pp. 1650-52). Consider for instance a two-state system O (say, a light-emitting diode, or l.e.d., which can be *on* or *off*) interacting with a two-state system S (say, the spin of an electron, which can be *up* or *down*). Assume the interaction is such that if the spin is *up* (*down*) the l.e.d. goes *on* (*off*). To start with, the electron can be in a superposition of its two states. In the account of the state of the electron that we can associate with the l.e.d., a quantum event happens in the interaction, the wave function of the electron collapses to one of two states, and the l.e.d. is then either *on* or *off*. But we can also consider the l.e.d./electron composite system as a quantum system and study the interactions of this composite system with another system O'. In the account associated to O', there is no event and no collapse at the time of the interaction, and the composite system is still in the superposition of the two states [spin *up*/l.e.d. *on*] and [spin *down*/l.e.d. *off*] after the interaction. It is necessary to assume this superposition because it accounts for measurable interference effects between the two states: if quantum mechanics is correct, these interference effects are truly observable by O'. So, we have two discordant accounts of the same events. Can the two discord accounts be compared and does the comparison lead to contradiction? They can be compared, because the information on the first account is stored in the state of the l.e.d. and O' has access to this information. Therefore O and O' can compare their accounts of the state of the world.

However, the comparison does not lead to contradiction *because the comparison is itself a physical process that must be understood in the context of quantum mechanics*. Indeed, O' can physically interact with the electron and then with the l.e.d. (or, equivalently, the other way around). If, for instance, he finds the spin of the electron *up*, quantum mechanics predicts that he will then consistently find the l.e.d. on (because in the first measurement the state of the composite system collapses on its [spin *up*/l.e.d. *on*] component). That is, the multiplicity of accounts leads to no contradiction precisely because the comparison between different accounts can only be a physical quantum interaction. This internal self-consistency of the quantum formalism is general, and it is perhaps its most remarkable aspect. This self consistency is taken in relational quantum mechanics as a strong indication of the relational nature of the world.

In fact, one may conjecture that this peculiar consistency between the observations of different observers is the missing ingredient for a reconstruction theorem of the Hilbert space formalism of quantum theory. Such a reconstruction theorem is still unavailable: On the basis of reasonable physical assumptions, one is able to derive the structure of an orthomodular lattice containing subsets that form Boolean algebras, which "almost", but not quite, implies the existence of a Hilbert space and its projectors' algebra (see the entry Quantum Logic and Quantum Probability.) Perhaps an appropriate algebraic formulation of the condition of consistency between subsystems could provide the missing hypothesis to complete the reconstruction theorem.

3. Correlations

The conceptual relevance of *correlations* in quantum mechanics, - a central aspect of relational quantum mechanics -- is emphasized by David Mermin, who analyses the statistical features of correlation

(Mermin 1998), and arrives at views close to the relational ones. Mermin points out that a theorem on correlations in Hilbert space quantum mechanics is relevant to the problem of what exactly quantum theory tells us about the physical world. Consider a quantum system *S* with internal parts *s*, s',…, that may be considered as subsystems of *S* , and define the correlations among subsystems as the expectation values of products of subsystems' observables. It can be proved that, for any resolution of *S* into subsystems, the subsystems' correlations determine *uniquely* the state of *S*. According to Mermin, this theorem highlights two major lessons that quantum mechanics teaches us: first, the relevant physics of *S* is entirely contained in the correlations both among the *s*, s',…, themselves (internal correlations) and among the s',…, and other systems (external correlations); second, correlations may be ascribed physical reality whereas, according to well-known 'no-go' theorems, the quantities that are the terms of the correlations cannot (Mermin 1998).

4. Self-reference and self-measurement

From a relational point of view, the properties of a system exists only in reference to another system. What about the properties of a system with respect to itself? Can a system measure itself? Is there any meaning of the correlations of a system with itself? Implicit in the relational point of view is the intuition that a complete self-measurement is impossible. It is this impossibility that forces all properties to be referred to another system. The issue of the self-measurement has been analyzed in details in two remarkable works, from very different perspectives, but with similar conclusions, by Marisa Dalla Chiara and by Thomas Breuer.

4.1 Logical aspect of the measurement problem

Marisa Dalla Chiara (1977) has addressed the *logical* aspect of the measurement problem. She observes that the problem of self-measurement in quantum mechanics is strictly related to the *self-reference* problem, which has an old tradition in logic. From a logical point of view the measurement problem of quantum mechanics can be described as a characteristic question of "semantical closure" of a theory. To what extent can quantum mechanics apply consistently to the objects and the concepts in terms of which its metatheory is expressed? Dalla Chiara shows that the duality in the description of state evolution, encoded in the ordinary (i.e. von Neumann's) approach to the measurement problem, can be given a purely logical interpretation: "If the apparatus observer *O* is an object of the theory, then *O* cannot realize the reduction of the wave function. This is possible only to another O', which is 'external' with respect to the universe of the theory. In other words, any apparatus, as a particular physical system, can be an object of the theory. Nevertheless, *any apparatus which realizes the reduction of the wave function is necessarily only a metatheoretical object* " (Dalla Chiara 1977, p. 340). This observation is remarkably consistent with the way in which the state vector reduction is justified within the relational interpretation of quantum mechanics. When the system *S*+*O* is considered from the point of view of O', the measurement can be seen as an interaction whose dynamics is fully unitary, whereas by the point of view of *O* the measurement breaks the unitarity of the evolution of *S*. The unitary evolution does not break down through mysterious physical jumps, due to unknown effects, but simply because *O* is not giving a full dynamical description of the interaction. *O* cannot have a full description of the interaction of *S* with

himself (*O*), because his information is correlation information and there is no meaning in being correlated with oneself. If we include the observer into the system, then the evolution is still unitary, but we are now dealing with the description of a different observer.

4.2 Impossibility of complete self-measurement

As is well known, from a purely logical point of view self-reference properties in formal systems impose limitations on the descriptive power of the systems themselves. Thomas Breuer has shown that, from a physical point of view, this feature is expressed by the existence of limitations in the universal validity of physical theories, *no matter whether classical or quantum* (Breuer 1995). Breuer studies the possibility for an apparatus *O* to measure its own state. More precisely, of measuring the state of a system *containing* an apparatus *O*. He defines a map from the space of all sets of states of the apparatus to the space of all sets of states of the system. Such a map assigns to every set of apparatus states the set of system states that is compatible with the information that -- after the measurement interaction -- the apparatus is in one of these states. Under reasonable assumptions on this map, Breuer is able to prove a theorem stating that no such map can exist that can distinguish all the states of the system. An apparatus *O* cannot distinguish all the states of a system *S* containing *O*. This conclusion holds irrespective of the classical or quantum nature of the systems involved, but in the quantum context it implies that no quantum mechanical apparatus can measure all the quantum correlations between *itself* and an external system. These correlations are only measurable by a second external apparatus, observing both the system and the first apparatus.

5. Other relational views

5.1 Quantum reference systems

A relational view of quantum mechanics has been proposed also by Gyula Bene (1997). Bene argues that quantum states are relative in the sense that they express a relation between a system to be described and a different system, containing the former as a subsystem and acting for it as a *quantum reference system* (here the system is contained in the reference system, while in Breuer's work the system contains the apparatus). Consider again a measuring system (*O*) that has become entangled with a measured system (*S*) during a measurement. Once again, the difficulty of quantum theory is that there is an apparent contradiction between the fact that the quantity *q* of the system assumes an observed value in the measurement, while the composite *S*+*O* system still has to be considered in a superposition state, if we want to properly predict the outcome of measurements on the *S*+*O* system. This apparent contradiction is resolved by Bene by relativizing the state not to an observer, as in the relational quantum mechanics sketched in Section 2, but rather to a relevant composite system. That is: there is a state of the system *S* relative to *S* alone, and a state of the system *S* relative to the *S*+*O* composite system. (Similarly, there is a state of the system *O* relative to itself alone, and a state of the system *O* relative to the *S*+*O* ensemble.) The ensemble with respect to which the state is defined is called by Bene the *quantum reference system* . The state of a system with respect to a given quantum reference system correctly predicts the probability

distributions of any measurement on the entire reference system. This dependence of the states of quantum systems from different quantum systems that act as reference systems is viewed as a fundamental property that holds no matter whether a system is observed or not.

5.2 Sigma algebra of interactive properties

Similar views have been expressed by Simon Kochen in unpublished but rather well-known notes (Kochen, 1979). In Kochen's words: "The basic change in the classical framework which we advocate lies in dropping the assumption of the absoluteness of physical properties of interacting systems... Thus quantum mechanical properties acquire an interactive or relational character." Kochen uses a σ-algebra formalism. Each quantum system has an associated Hilbert space. The properties of the system are established by its interaction with other quantum systems, and these properties are represented by the corresponding projection operators on the Hilbert space. These projectors are elements of a Boolean σ-algebra, determined by the physics of the interaction between the two systems. Suppose a quantum system S can interact with quantum systems Q, Q',…. In each case, S will acquire an interaction σ-algebra of properties $\sigma(Q)$, $\sigma(Q')$ since the interaction between S and Q may be finer grained than the interaction between S and Q'. Thus, interaction σ-algebras may have non-trivial intersections. The *family* of all Boolean σ-algebras forms a category, with the sets of the projectors of each σ-algebra as objects. In Kochen's words: "Just as the state of a composite system does not determine states of its components, conversely, the states of the... correlated systems do not determine the state of the composite system [...] We thus resolve the measurement problem by cutting the Gordian knot tying the states of component systems uniquely to the state of the combined system." This is very similar in spirit to the Bene approach. The precise relation between Kochen's approach and Rovelli's relational quantum mechanics has been analysed by Bill Curry (1999).

Further approaches at least formally related to Kochen's have been proposed by Healey (1989), who also emphasises an interactive aspect of his approach, and by Dieks (1989). See also the entry on 'Modal Interpretations of Quantum Mechanics'.

5.3 Quantum theory of the universe

Relational views on quantum theory have been defended also by Lee Smolin (1995) and by Louis Crane (1995) in a cosmological context. If one is interested in the quantum theory of the entire universe, then, by definition, an external observer is not available. Breuer's theorem shows then that a quantum state of the universe, containing all correlations between all subsystems, expresses information that is not available, not even in principle, to any observer. In order to write a meaningful quantum state, argue Crane and Smolin, we have to divide the universe in two components and consider the relative quantum state predicting the outcomes of the observations that one component can make on the other.

5.4 Relation with Everett's relative-state interpretation

Relational ideas underlie also the interpretations of quantum theory inspired by the work of Everett. Everett' original work (Everett 1975) relies on the notion of "relative state" and has a marked relational tone (see quantum mechanics: Everett's relative-state formulation of). In the context of Everettian accounts, a state may be taken as relative either (more commonly) to a "world", or "branch", or (sometimes) to the state of another system (see for instance Saunders 1996, 1998). While the first variant (relationalism with respect to branches) is far from the relational views described here, the second variant (relationalism with respect to the state of a system) is closer.

However, it is different to say that something is relative to a system or that something is relative to a state of a system. Consider for instance the situation described in the example of Section 5: According to the relational interpretation, after the first measurement the quantity q has a given value and only one for O, while in Everettian terms the quantity q has a value for one state of O and a different value for another state of O, and the two are equally real. In Everett, there is an ontological multiplicity of realities, which is absent in the relational point of view, where physisical quantities are uniquely determined, once two systems are given.

The difference derives from a very general interpretational difference between Everettian accounts and the relational point of view. Everett (at least in its widespread version) takes the state Ψ as the basis of the ontology of quantum theory. The overall state Ψ includes different possible branches and different possible outcomes. On the other hand, the relational interpretation takes the quantum events q, that is, the actualizations of values of physical quantities, as the basic elements of reality (see Section 1.1 above) and such q's are assumed to be univocal. The relational view avoids the traditional difficulties in taking the q's as univocal simply by noticing that a q does not refer to a system, but rather to a pair of systems.

For a comparison between the relational interpretation and other current interpretations of quantum mechanics, see Rovelli 1996.

6. Some consequences of the relational point of view

A number of open conceptual issues in quantum mechanics appear in a different light when seen in the context of a relational interpretation of the theory. For instance, the conventional conclusions of the Einstein-Podolsky-Rosen argument turn out to be frame-dependent, and this result supports the "peaceful coexistence" of quantum mechanics and special relativity (Laudisa 2001). In certain istances, the descriptions given in different Lorentz frames can be identified with descriptions relative to different observer systems, which are consistent in the sense of Section 2.

Also, the relational interpretation allows one to give a precise definition of the time (or, better, the probability distribution of the time) at which a measurement happens, in terms of the probability distribution of the correlation between system and apparatus, as measurable by a third observer (Rovelli 1998).

Finally, it has been suggested in (Rovelli 1997) that the relationalism at the core of quantum theory pointed out by the relational interpretations might be connected with the spatiotemporal relationalism that characterizes general relativity. Quantum mechanical relationalism is the observation that there are no absolute properties: properties of a system *S* are relative to another system *O* with which *S* is interacting. General relativistic relationalism is the well known observation that there is no absolute localization in spacetime: localization of an object *S* in spacetime is only relative to the gravitational field, or to any other object *O*, to which *S* is contiguous. There is a connection between the two, since interaction between *S* and *O* implies contiguity and contiguity between *S* and *O* can only be checked via some *quantum* interaction. However, because of the difficulty of developing a consistent and conceptually transparent theory of quantum gravity, so far this suggestion has not been developed beyond the stage of a simple intuition.

7. Conclusion

Relational interpretations of quantum mechanics propose a solution to the interpretational difficulties of quantum theory based on the idea of weakening the notions of the state of a system, event, and the idea that a system, at a certain time, may just have a certain property. The world is described as an ensemble of events ("the electron is the point *x*") which happen only *relatively to* a given observer. Accordingly, the state and the properties of a system are relative to another system only. There is a wide diversity in style, emphasis, and language in the authors that we have mentioned. Indeed, most of the works mentioned have developed independently from each other. But it is rather clear that there is a common idea underlying all these approaches, and the convergence is remarkable.

Werner Heisenberg first recognized that the electron does not have a well defined position when it is not interacting. Relational interpretations push this intuition further, by stating that, even when interacting, the position of the electron is only determined in relation to a certain observer, or to a certain quantum reference system, or similar.

In physics, the move of deepening our insight into the physical world by relativizing notions previously used as absolute has been applied repeatedly and very successfully. Here are a few examples. The notion of the velocity of an object has been recognized as meaningless, unless it is indexed with a reference body with respect to which the object is moving. With special relativity, simultaneity of two distant events has been recognized as meaningless, unless referred to a specific state of motion of something. (This something is usually denoted as "the observer" without, of course, any implication that the observer is human or has any other peculiar property besides having a state of motion. Similarly, the "observer system" *O* in quantum mechanics need not to be human or have any other property beside the possibility of interacting with the "observed" system *S*.) With general relativity, the position in space and time of an object has been recognized as meaningless, unless it is referred to the gravitational field, or to some other dynamical physical entity. The move proposed by the relational interpretations of quantum mechanics has strong analogies with these, but is, in a sense, a longer jump, since all physical events and the entirety of the contingent properties of any physical system are taken to be meaningful only as relative to a

second physical system. The claim of the relational interpretations is that this is not an arbitrary move. Rather, it is a conclusion which is difficult to escape, following from the observation -- explained above in the example of the "second observer" -- that a variable (of a system *S*) can have a well determined value *q* for one observer (*O*) and at the same time fail to have a determined value for another observer (*O*′).

This way of thinking the world has certainly heavy philosophical implications. The claim of the relational interpretations is that it is nature itself that is forcing us to this way of thinking. If we want to understand nature, our task is not to frame nature into our philosophical prejudices, but rather to learn how to adjust our philosophical prejudices to what we learn from nature.

The Identity Theory of Mind

The identity theory of mind holds that states and processes of the mind are identical to states and processes of the brain. Strictly speaking, it need not hold that the mind is identical to the brain. Idiomatically we do use ‘She has a good mind’ and ‘She has a good brain’ interchangeably but we would hardly say ‘Her mind weighs fifty ounces’. Here I take identifying mind and brain as being a matter of identifying processes and perhaps states of the mind and brain. Consider an experience of pain, or of seeing something, or of having a mental image. The identity theory of mind is to the effect that these experiences just *are* brain processes, not merely *correlated with* brain processes.

Some philosophers hold that though experiences are brain processes they nevertheless have fundamentally non-physical, psychical, properties, sometimes called ‘qualia’. Here I shall take the identity theory as denying the existence of such irreducible non-physical properties. Some identity theorists give a behaviouristic analysis of mental *states*, such as beliefs and desires, but others, sometimes called ‘central state materialists’, say that mental states are actual brain states. Identity theorists often describe themselves as ‘materialists’ but ‘physicalists’ may be a better word. That is, one might be a materialist about mind but nevertheless hold that there are entities referred to in physics that are not happily described as ‘material’.

In taking the identity theory (in its various forms) as a species of physicalism, I should say that this is an ontological, not a translational physicalism. It would be absurd to try to translate sentences containing the word ‘brain’ or the word ‘sensation’ into sentences about electrons, protons and so on. Nor can we so translate sentences containing the word ‘tree’. After all ‘tree’ is largely learned ostensively, and is not even part of botanical classification. If we were small enough a dandelion might count as a tree. Nevertheless a physicalist could say that trees are complicated physical mechanisms. The physicalist will deny strong emergence in the sense of some philosophers, such as Samuel Alexander and possibly C.D. Broad . The latter remarked (Broad 1937) that as far as was known at that time the properties of common salt cannot be deduced from the properties of sodium in isolation and of chlorine in isolation. (He put it too epistemologically: chaos theory shows that even in a deterministic theory theory physical consequences can outrun predictability.) Of course the physicalist will not deny the harmless sense of "emergence" in which an apparatus is not just a jumble of its parts (Smart 1981).

Historical Antecedents

The identity theory as I understand it here goes back to U.T. Place and Herbert Feigl in the 1950s. Historically philosophers and scientists, for example Leucippus, Hobbes, La Mettrie, and d'Holbach, as well as Karl Vogt who made the preposterous remark (perhaps not meant to be taken too seriously) that the brain secretes thought as the liver secretes bile, have embraced materialism. However, here I shall date interest in the identity theory from the pioneering papers ‘Is Consciousness a Brain Process?’ by U.T. Place (Place 1956) and H. Feigl ‘The "Mental" and the "Physical"’ (Feigl 1958). Nevertheless mention should be made of suggestions by Rudolf Carnap (1932, p. 127), H. Reichenbach (1938) and M. Schlick (1935). Reichenbach said that mental events can be identified by the corresponding stimuli and responses much as the (possibly unknown) internal state of a photo-electric cell can be identified by the stimulus (light falling on it) and response (electric current flowing) from it. In both cases the internal states can be physical states. However Carnap did regard the identity as a linguistic recommendation rather than as asserting a question of fact. See his ‘Herbert Feigl on Physicalism’ in Schilpp (1963), especially p. 886. The psychologist E.G. Boring (1933) may well have been the first to use the term ‘identity theory’. See Place (1990).

Place's very original and pioneering paper was written after discussions at the University of Adelaide with Smart and C.B. Martin. For recollections of Martin's contributions to the discussion see Place (1989) ‘Low Claim Assertions’ in Heil (1989). Smart at the time argued for a behaviourist position in which mental events were elucidated purely in terms of hypothetical propositions about behaviour, as well as first person reports of experiences which Gilbert Ryle regarded as ‘avowals’. Avowals were thought of as mere pieces of behaviour, as if saying that one had a pain was just doing a sophisticated sort of wince. Smart saw Ryle's theory as friendly to physicalism though that was not part of Ryle's motivation. Smart hoped that the hypotheticals would ultimately be explained by neuroscience and cybernetics. Being unable to refute Place, and recognizing the unsatisfactoriness of Ryle's treatment of inner experience, to some extent recognized by Ryle himself (Ryle 1949, p. 240), Smart soon became converted to Place's view (Smart 1959). In this he was also encouraged and influenced by Feigl's ‘"The Mental" and the "Physical" ’ (Feigl 1958, 1967). Feigl's wide ranging contribution covered many problems, including those connected with intentionality, and he introduced the useful term ‘nomological danglers’ for the dualists' supposed mental-physical correlations. They would dangle from the

nomological net of physical science and should strike one as implausible excrescences on the fair face of science. Feigl (1967) contains a valuable ‘Postscript’.

The Nature of the Identity Theory

Place spoke of constitution rather than of identity. One of his examples is ‘This table is an old packing case’. Another is ‘lightning is an electric discharge’. Indeed this latter was foreshadowed by Place in his earlier paper ‘The Concept of Heed’ (Place 1954), in which he took issue with Ryle's behaviourism as it applied to concepts of consciousness, sensation and imagery. Place remarked (p. 255)

> The logical objections which might be raised to the statement ‘consciousness is a process in the brain’ are no greater than the logical objections which might be raised to the statement ‘lightning is a motion of electric charges’.

It should be noticed that Place was using the word ‘logical’ in the way that it was used at Oxford at the time, not in the way that it is normally used now. One objection was that ‘sensation’ does not mean the same as ‘brain process’. Place's reply was to point out that ‘this table’ does not mean the same as ‘this old packing case’ and ‘lightning’ does not mean the same as ‘motion of electric charges’. We find out whether this is a table in a different way from the way in which we find out that it is an old packing case. We find out whether a thing is lightning by looking and that it is a motion of electric charges by theory and experiment. This does not prevent the table being identical with the old packing case and the perceived lightning being nothing other than an electric discharge. Feigl and Smart put the matter more in terms of the distinction between meaning and reference. ‘Sensation’ and ‘brain process’ may differ in meaning and yet have the same reference. ‘Very bright planet seen in the morning’ and ‘very bright planet seen in the evening’ both refer to the same entity Venus. (Of course these expressions *could* be construed as referring to different things, different sequences of temporal stages of Venus, but not necessarily or most naturally so.)

There did seem to be a tendency among philosophers to have thought that identity statements needed to be necessary and a priori truths. However identity theorists have treated ‘sensations are brain processes’ as contingent. We had to *find out* that the identity holds. Aristotle, after all, thought that the brain was for cooling the blood. Descartes thought that consciousness is immaterial.

It was sometimes objected that sensation statements are incorrigible whereas statements about brains are corrigible. The inference was made that there must be something different about sensations. Ryle and in effect Wittgenstein toyed with the attractive but quite implausible notion that ostensible reports of immediate experience are not really reports but are ‘avowals’, as if my report that I have toothache is just a sophisticated sort of wince. Place, influenced by Martin, was able to explain the relative incorrigibility of sensation statements by their low claims: ‘I see a bent oar’ makes a bigger claim than ‘It looks to me that there is a bent oar’. Nevertheless my sensation and my putative awareness of the sensation are distinct existences and so, by Hume's principle, it must be possible for one to occur without the other. One should deny anything other than a relative incorrigibility (Place 1989).

As remarked above, Place preferred to express the theory by the notion of constitution, whereas Smart preferred to make prominent the notion of identity as it occurs in the axioms of identity in logic. So Smart had to say that if sensation X is identical to brain process Y then if Y is between my ears and is straight or circular (absurdly to oversimplify) then the sensation X is between my ears and is straight or circular. Of course it is not presented to us as such in experience. Perhaps only the neuroscientist could know that it is straight or circular. The professor of anatomy might be identical with the dean of the medical school. A visitor might know that the professor hiccups in lectures but not know that the dean hiccups in lectures.

Phenomenal Properties and Topic-Neutral Analyses

Someone might object that the dean of the medical school does not *qua* dean hiccup in lectures. *Qua* dean he goes to meetings with the vice-chancellor. This is not to the point but there is a point behind it. This is that *the property* of being the professor of anatomy is not identical with *the property* of being the dean of the medical school. The question might be asked, that even if sensations are identical with brain processes, are there not introspected non-physical properties of sensations that are not identical with properties of brain processes? How would a physicalist identity theorist deal with this? The answer (Smart 1959) is that the properties of experiences are 'topic neutral'. Smart adapted the words 'topic-neutral' from Ryle, who used them to characterise words such as 'if, 'or', 'and', 'not', 'because'. If you overheard only these words in a conversation you would not be able to tell whether the conversation was one of mathematics, physics, geology, history, theology, or any other subject. Smart used the words 'topic neutral' in the narrower sense of being neutral between physicalism and dualism. For example 'going on', 'occurring', 'intermittent', 'waxing', 'waning' are topic neutral. So is 'me' in so far as it refers to the utterer of the sentence in question. Thus to say that a sensation is caused by lightning or the presence of a cabbage before my eyes leaves it open as to whether the sensation is non-physical as the dualist believes or is physical as the materialist believes. This sentence also is neutral as to whether the properties of the sensation are physical or whether some of them are irreducibly psychical. To see how this idea can be applied to the present purpose let us consider the following example.

Suppose that I have a yellow, green and purple striped mental image. We may also introduce the philosophical term 'sense datum' to cover the case of seeing or seeming to see something yellow, green and purple: we say that we have a yellow, green and purple sense datum. That is I would see or seem to see, for example, a flag or an array of lamps which is green, yellow and purple striped. Suppose also, as seems plausible, that there is nothing yellow, green and purple striped in the brain. Thus it is important for identity theorists to say (as indeed they have done) that sense data and images are not part of the furniture of the world. 'I have a green sense datum' is really just a way of saying that I see or seem to see something that really is green. This move should not be seen as merely an *ad hoc* device, since Ryle and J.L. Austin, in effect Wittgenstein, and others had provided arguments, as when Ryle argued that mental images were not a sort of ghostly picture postcard. Place characterised the fallacy of thinking that when we perceive something green we are perceiving something green in the mind as 'the phenomenological fallacy'. He characterizes this fallacy (Place 1956):

> the mistake of supposing that when the subject describes his experience, when he describes how things look, sound, smell, taste, or feel to him, he is describing the literal properties of objects and events on a peculiar sort of internal cinema or television screen, usually referred to in the modern psychological literature as the ‘phenomenal field’.

Of course, as Smart recognised, this leaves the identity theory dependent on a physicalist account of colour . His early account of colour (1961) was too behaviourist, and could not deal, for example, with the reversed spectrum problem, but he later gave a realist and objectivist account (Smart 1975). Armstrong had been realist about colour but Smart worried that if so colour would be a very idiosyncratic and disjunctive concept, of no cosmic importance, of no interest to extraterrestrials (for instance) who had different visual systems. Prompted by Lewis in conversation Smart came to realize that this was no objection to colours being objective properties.

One first gives the notion of a normal human percipient with respect to colour for which there are objective tests in terms of ability to make discriminations with respect to colour. This can be done without circularity. Thus ‘discriminate with respect to colour’ is a more primitive notion than is that of colour. (Compare the way that in set theory ‘equinumerous’ is antecedent to ‘number’.) Then Smart elucidated the notion of colour in terms of the discriminations with respect to colour of normal human percipients in normal conditions (say cloudy Scottish daylight). This account of colour may be disjunctive and idiosyncratic. (Maxwell's equations might be of interest to Alpha Centaurians but hardly our colour concepts.) Anthropocentric and disjunctive they may be, but objective none the less. David R. Hilbert (1987) identifies colours with reflectances, thus reducing the idiosyncrasy and disjunctiveness. A few epicycles are easily added to deal with radiated light, the colours of rainbows or the sun at sunset and the colours due to diffraction from feathers. John Locke was on the right track in making the secondary qualities objective as powers in the object, but erred in making these powers to be powers to produce ideas in the mind rather than to make behavioural discriminations. (Also Smart would say that if powers are dispositions we should treat the secondary qualities as the categorical bases of these powers, e.g. in the case of colours properties of the surfaces of objects.) Locke's view suggested that the ideas have mysterious qualia observed on the screen of an internal mental theatre. However to do Locke justice he does not talk in effect of ‘red ideas’ but of ‘ideas of red’. Philosophers who elucidate ‘is red’ in terms of ‘looks red’ have the matter the wrong way round (Smart 1995).

Let us return to the issue of us having a yellow, purple and green striped sense datum or mental image and yet there being no yellow, purple and green striped thing in the brain. The identity theorist (Smart 1959) can say that sense data and images are not real things in the world: they are like the average plumber. Sentences ostensibly about the average plumber can be translated into, or elucidated in terms of, sentences about plumbers. So also there is having a green sense datum or image but not sense data or images, and the having of a green sense datum or image is not itself green. So it can, so far as this goes, easily be a brain process which is not green either.

Thus Place (1956, p. 49):

> When we describe the after-image as green... we are saying that we are having the sort of experience which we normally have when, and which we have learned to described as, looking at a green patch of light.

and Smart (1959) says:

> When a person says ‘I see a yellowish-orange after-image’ he is saying something like this: "*There is something going on which is like what is going on when* I have my eyes open, am awake, and there is an orange illuminated in good light in front of me".

Quoting these passages, David Chalmers (1996, p. 360) objects that if ‘something is going on’ is construed broadly enough it is inadequate, and if it is construed narrowly enough to cover only experiential states (or processes) it is not sufficient for the conclusion. Smart would counter this by stressing the word ‘typically’. Of course a lot of things go on in me when I have a yellow after image (for example my heart is pumping blood through my brain). However they do not *typically* go on then: they go on at other times too. Against Place Chalmers says that the word ‘experience’ is unanalysed and so Place's analysis is insufficient towards establishing an identity between sensations and brain processes. As against Smart he says that leaving the word ‘experience’ out of the analysis renders it inadequate. That is, he does not accept the ‘topic-neutral’ analysis. Smart hopes, and Chalmers denies, that the account in terms of ‘typically of’ saves the topic-neutral analysis. In defence of Place one might perhaps say that it is not clear that the word ‘experience’ cannot be given a topic neutral analysis, perhaps building on Farrell (1950). If we do not need the word ‘experience’ neither do we need the word ‘mental’. Rosenthal (1994) complains (against the identity theorist) that experiences have some characteristically mental properties, and that ‘We inevitably lose the distinctively mental if we construe these properties as neither physical nor mental’. Of course to be topic neutral is to be able to be both physical and mental, just as arithmetic is. There is no need for the word ‘mental’ itself to occur in the topic neutral formula. ‘Mental’, as Ryle (1949) suggests, in its ordinary use is a rather grab-bag term, ‘mental arithmetic’, ‘mental illness’, etc. with which an identity theorist finds no trouble.

Causal Role Theories

In their accounts of mind, David Lewis and D.M. Armstrong emphasise the notion of causality. Lewis's 1966 was a particularly clear headed presentation of the identity theory in which he says (I here refer to the reprint in Lewis 1983, p. 100):

> My argument is this: The definitive characteristic of any (sort of) experience as such is its causal role, its syndrome of most typical causes and effects. But we materialists believe that these causal roles which belong by analytic necessity to experiences belong in fact to certain physical states. Since these physical states possess the definitive character of experiences, they must be experiences.

Similarly, Robert Kirk (1999) has argued for the impossibility of zombies. If the supposed zombie has all the behavioural and neural properties ascribed to it by those who argue from the possibility of zombies against materialism, then the zombie is conscious and so not a zombie.

Thus there is no need for explicit use of Ockham's Razor as in Smart (1959) though not in Place (1956). (See Place 1960.) Lewis's paper was extremely valuable and already there are hints of a marriage between the identity theory of mind and so-called ‘functionalist’ ideas that are explicit in Lewis 1972 and 1994. In his 1972 (‘Psychophysical and Theoretical Identifications’) he applies ideas in his more formal paper ‘How to Define Theoretical Terms’ (1970). Folk psychology contains words such as ‘sensation’, ‘perceive’, ‘belief, ‘desire’, ‘emotion’, etc. which we recognise as psychological. Words for colours, smells, sounds, tastes and so on also occur. One can regard common sense platitudes containing both these sorts of these words as constituting a theory and we can take them as theoretical terms of common sense psychology and thus as denoting whatever entities or sorts of entities uniquely realise the theory. Then if certain neural states do so too (as we believe) then the mental states must be these neural states. In his 1994 he allows for tact in extracting a consistent theory from common sense. One cannot uncritically collect platitudes, just as in producing a grammar, implicit in our speech patterns, one must allow for departures from what on our best theory would constitute grammaticality.

A great advantage of this approach over the early identity theory is its holism. Two features of this holism should be noted. One is that the approach is able to allow for the causal interactions between brain states and processes themselves, as well as in the case of external stimuli and responses. Another is the ability to draw on the notion of Ramseyfication of a theory. F.P. Ramsey had shown how to replace the theoretical terms of a theory such as ‘the property of being an electron’ by ‘the property X such that...’. so that when this is done for all the theoretical terms, we are left only with ‘property X such that’, ‘property Y such that’ etc. Take the terms describing behaviour as the observation terms and psychological terms as the theoretical ones of folk psychology. Then Ramseyfication shows that folk psychology is compatible with materialism. This seems right, though perhaps the earlier identity theory deals more directly with reports of immediate experience.

The causal approach was also characteristic of D.M. Armstrong's careful conceptual analysis of mental states and processes, such as perception and the secondary qualities, sensation, consciousness, belief, desire, emotion, voluntary action, in his *A Materialist Theory of the Mind* (1968a) with a second edition (1993) containing a valuable new preface. Parts I and II of this book are concerned with conceptual analysis, paving the way for a contingent identification of mental states and processes with material ones. As had Brian Medlin, in an impressive critique of Ryle and defence of materialism (Medlin 1967), Armstrong preferred to describe the identity theory as ‘Central State Materialism’. Independently of Armstrong and Lewis, Medlin's central state materialism depended, as theirs did, on a causal analysis of concepts of mental states and processes. See Medlin 1967, and 1969 (including endnote 1).

Mention should particularly be made here of two of Armstrong's other books, one on perception (1961), and one on bodily sensations, (1962). Armstrong thought of perception as *coming to believe by means of the senses* (compare also Pitcher 1971). This combines the advantages of Direct Realism with hospitality towards the scientific causal story which had been thought to have supported the earlier representative

theory of perception. Armstrong regarded bodily sensations as perceptions of states of our body. Of course the latter may be mixed up with emotional states, as an itch may include a propensity to scratch, and contrariwise in exceptional circumstances pain may be felt without distress. However, Armstrong sees the central notion here as that of perception. This suggests a terminological problem. Smart had talked of visual sensations. These were not perceptions but something which occurred in perception. So in *this* sense of ‘sensation’ there should be bodily sensation sensations. The ambiguity could perhaps be resolved by using the word ‘sensing’ in the context of ‘visual’, ‘auditory’, ‘tactile’ and ‘bodily’, so that bodily sensations would be perceivings which involved introspectible ‘sensings’. These bodily sensations are perceptions and there can be misperceptions as when a person with his foot amputated can think that he has a pain in the foot. He has a sensing ‘having a pain in the foot’ but the world does not contain a pain in the foot, just as it does not contain sense data or images but does contain havings of sense data and of images.

Armstrong's central state materialism involved identifying beliefs and desires with states of the brain (1968a). Smart came to agree with this. On the other hand Place resisted the proposal to extend the identity theory to dispositional states such as beliefs and desires. He stressed that we do not have privileged access to our beliefs and desires. Like Ryle he thought of beliefs and desires as to be elucidated by means of hypothetical statements about behaviour and gave the analogy of the horsepower of a car (Place 1967). However he holds that the dispute here is not so much about the neural basis of mental states as about the nature of dispositions. His views on dispositions are argued at length in his debate with Armstrong and Martin (Armstrong, Martin and Place, T. Crane (ed.) 1996). Perhaps we can be relaxed about whether mental states such as beliefs and desires are dispositions or are topic neutrally described neurophysiological states and return to what seems to be the more difficult issue of consciousness. Causal identity theories are closely related to Functionalism, to be discussed in the next section. Smart had been wary of the notion of causality in metaphysics believing that it had no place in theoretical physics. However even so he should have admitted it in folk psychology and also in scientific psychology and biology generally, in which physics and chemistry are applied to explain generalisations rather than strict laws. If folk psychology uses the notion of causality, it is no matter if it is what Quine has called second grade discourse, involving the very contextual notions of modality.

Functionalism and Identity Theory

It has commonly been thought that the identity theory has been superseded by a theory called ‘functionalism’. It could be argued that functionalists greatly exaggerate their difference from identity theorists. Indeed some philosophers, such as Lewis (1972 and 1994) and Jackson, Pargetter and Prior (1982), see functionalism as a route towards an identity theory.

Like Lewis and Armstrong, functionalists define mental states and processes in terms of the their causal relations to behaviour but stop short of identifying them with their neural realisations. Of course the term ‘functionalism’ has been used vaguely and in different ways, and it could be argued that even the theories of Place, Smart and Armstrong were at bottom functionalist. The word ‘functionalist’ has affinities with that of ‘function’ in mathematics and also with that of ‘function’ in biology. In mathematics a function is

a set of ordered n-tuples. Similarly if mental processes are defined directly or indirectly by sets of stimulus-response pairs the definitions could be seen as ‘functional’ in the mathematical sense. However there is probably a closer connection with the term as it is used in biology, as one might define ‘eye’ by its function even though a fly's eye and a dog's eye are anatomically and physiologically very different. Functionalism identifies mental states and processes by means of their causal roles, and as noted above in connection with Lewis, we know that the functional roles are possessed by neural states and processes. (There are teleological and homuncular forms of functionalism, which I do not consider here.) Nevertheless an interactionist dualist such as the eminent neurophysiologist Sir John Eccles would (implausibly for most of us) deny that all functional roles are so possessed. One might think of folk psychology, and indeed much of cognitive science too, as analogous to a ‘block diagram’ in electronics. A box in the diagram might be labelled (say) ‘intermediate frequency amplifier’ while remaining) neutral as to the exact circuit and whether the amplification is carried out by a thermionic valve or by a transistor. Using terminology of F. Jackson and P. Pettit (1988, pp. 381-400) the ‘role state’ would be given by ‘amplifier’, the ‘realiser state’ would be given by ‘thermionic valve’, say. So we can think of functionalism as a ‘black box’ theory. This line of thought will be pursued in the next section.

Thinking very much in causal terms about beliefs and desires fits in very well not only with folk psychology but also with Humean ideas about the motives of action. Though this point of view has been criticised by some philosophers it does seem to be right, as can be seen if we consider a possible robot aeroplane designed to find its way from Melbourne to Sydney. The designer would have to include an electronic version of something like a map of south-eastern Australia. This would provide the ‘belief’ side. One would also have to program in an electronic equivalent of ‘go to Sydney’. This program would provide the ‘desire’ side. If wind and weather pushed the aeroplane off course then negative feedback would push the aeroplane back on to the right course for Sydney. The existence of purposive mechanisms has at last (I hope) shown to philosophers that there is nothing mysterious about teleology. Nor are there any great semantic problems over intentionality (with a ‘t’). Consider the sentence ‘Joe desires a unicorn’. This is not like ‘Joe kicks a football’. For Joe to kick a football there must be a football to be kicked, but there are no unicorns. However we can say ‘Joe desires-true of himself "possesses a unicorn" ’. Or more generally ‘Joe believes-true S’ or ‘Joe desires-true S’ where S is an appropriate sentence (Quine 1960, pp. 206-16). Of course if one does not want to relativise to a language one needs to insert ‘or some samesayer of S’ or use the word ‘proposition’, and this involves the notion of proposition or intertranslatability. Even if one does not accept Quine's notion of indeterminacy of translation, there is still fuzziness in the notions of ‘belief’ and ‘desire’ arising from the fuzziness of ‘analyticity’ and ‘synonymy’. The identity theorist could say that on any occasion this fuzziness is matched by the fuzziness of the brain state that constitutes the belief or desire. Just how many interconnections are involved in a belief or desire? On a holistic account such as Lewis's one need not suppose that individuation of beliefs and desires is precise, even though good enough for folk psychology and Humean metaethics. Thus the way in which the brain represents the world might not be like a language. The representation might be like a map. A map relates every feature on it to every other feature. Nevertheless maps contain a finite amount of information. They have not infinitely many parts, still less continuum many. We can think of beliefs as expressing the different bits of information that could be extracted from the map. Thinking in this way beliefs would correspond near enough to the individualist beliefs characteristic of folk and Humean psychology.

Type and Token Identity Theories

The notion ‘type’ and ‘token’ here comes by analogy from ‘type’ and ‘token’ as applied to words. A telegram ‘love and love and love’ contains only two type words but in another sense, as the telegraph clerk would insist, it contains five words (‘token words’). Similarly a particular pain (more exactly a having a pain) according to the token identity theory is identical to a particular brain process. A functionalist could agree to this. Functionalism came to be seen as an improvement on and as inconsistent with the identity theory because of the correct assertion that a functional state can be realised by quite different brain states: thus a functional state might be realised by a silicon based brain as well as by a carbon based brain, and leaving robotics or science fiction aside, my feeling of toothache could be realised by a different neural process from what realises your toothache.

As far as this goes, at any rate, a functionalist can accept token identities. Functionalists commonly deny type identities. However Jackson, Pargetter and Prior (1982) and Braddon-Mitchell and Jackson (1996) argue that this is an over-reaction on the part of the functionalist. (Indeed they see functionalism as a route to the identity theory.) The functionalist may define mental states as having some state or other (e.g., carbon based or silicon based) which accounts for the functional properties. The functionalist second order state is a state of having some first order state or other which causes or is caused by the behaviour to which the functionalist alludes. In this way we have a second order type theory. Compare brittleness. The brittleness of glass and the brittleness of biscuits are both the state of having some property which explains their breaking, though the first order physical property may be different in the two cases. This way of looking at the matter is perhaps more plausible in relation to mental states such as beliefs and desires than it is to immediately reported experiences. When I report a toothache I do seem to be concerned with first order properties, even though topic neutral ones.

If we continue to concern ourselves with first order properties, we could say that the type-token distinction is not an all or nothing affair. We could say that human experiences are brain processes of one lot of sorts and Alpha Centaurian experiences are brain processes of another lot of sorts. We could indeed propose much finer classifications without going to the limit of mere token identities.

How restricted should be the restriction of a restricted type theory? How many hairs must a bald man have no more of? An identity theorist would expect his toothache today to be very similar to his toothache yesterday. He would expect his toothache to be quite similar to his wife's toothache. He would expect his toothache to be somewhat similar to his cat's toothache. He would not be confident about similarity to an extra-terrestrial's pain. Even here, however, he might expect some similarities of wave form or the like.

Even in the case of the similarity of my pain now to my pain ten minutes ago, there will be unimportant dissimilarities, and also between my pain and your pain. Compare topiary, making use of an analogy exploited by Quine in a different connection. In English country gardens the tops of box hedges are often cut in various shapes, for example peacock shapes. One might make generalizations about peacock

shapes on box hedges, and one might say that all the imitation peacocks on a particular hedge have the same shape. However if we approach the two imitation peacocks and peer into them to note the precise shapes of the twigs that make them up we will find differences. Whether we say that two things are similar or not is a matter of abstractness of description. If we were to go to the limit of concreteness the types would shrink to single membered types, but there would still be no ontological difference between identity theory and functionalism.

An interesting form of token identity theory is the anomalous monism of Davidson 1980. Davidson argues that causal relations occur under the neural descriptions but not under the descriptions of psychological language. The latter descriptions use intentional predicates, but because of indeterminacy of translation and of interpretation, these predicates do not occur in law statements. It follows that mind-brain identities can occur only on the level of individual (token) events. It would be beyond the scope of the present essay to consider Davidson's ingenious approach, since it differs importantly from the more usual forms of identity theory.

Consciousness

Place answered the question ‘Is Consciousness a Brain Process?’ in the affirmative. But what sort of brain process? It is natural to feel that there is something ineffable about which no mere neurophysiological process (with only physical intrinsic properties) could have. There is a challenge to the identity theorist to dispel this feeling.

Suppose that I am riding my bicycle from my home to the university. Suddenly I realise that I have crossed a bridge over a creek, gone along a twisty path for half a mile, avoided oncoming traffic, and so on, and yet have no memories of all this. In one sense I was conscious: I was perceiving, getting information about my position and speed, the state of the bicycle track and the road, the positions and speeds of approaching cars, the width of the familiar narrow bridge. But in another sense I was not conscious: I was on ‘automatic pilot’. So let me use the word ‘awareness’ for this automatic or subconscious sort of consciousness. Perhaps I am not one hundred percent on automatic pilot. For one thing I might be absent minded and thinking about philosophy. Still, this would not be relevant to my bicycle riding. One might indeed wonder whether one is ever one hundred percent on automatic pilot, and perhaps one hopes that one isn't, especially in Armstrong's example of the long distance truck driver (Armstrong 1962). Still it probably does happen, and if it does the driver is conscious only in the sense that he or she is alert to the route, of oncoming traffic etc., i.e. is perceiving in the sense of ‘coming to believe by means of the senses’. The driver gets the beliefs but is not aware of doing so. There is no suggestion of ineffability in this sense of ‘consciousness’, for which I shall reserve the term ‘awareness’.

For the full consciousness, the one that puzzles us and suggests ineffability, we need the sense elucidated by Armstrong in a debate with Norman Malcolm (Armstrong and Malcolm 1962, p. 110). Somewhat similar views have been expressed by other philosophers, such as Savage (1976), Dennett (1991), Lycan (1996), Rosenthal (1996). In the debate with Norman Malcolm, Armstrong compared consciousness with proprioception. In recent conversation he was prepared to say that it *is* proprioception. A case of

proprioception occurs when with our eyes shut and without touch we are immediately aware of the angle at which one of our elbows is bent. That is, proprioception is a special sense, different from that of bodily sensation, in which we become aware of parts of our body. Now the brain is part of our body and so perhaps immediate awareness of a process in or a state of our brain deserves to be called ‘proprioception’. Thus the proprioception which constitutes consciousness, as distinguished from mere awareness, is a higher order awareness, a perception of one part of (or configuration in) our brain by the brain itself. Some may sense circularity here. If so let them suppose that the proprioception occurs in an in practice negligible time after the process proprioceptd. Then perhaps there can be proprioceptions of proprioceptions, proprioceptions of proprioceptions of proprioceptions, and so on up, though in fact the sequence will probably not go up more than two or three steps. The last proprioception in the sequence will not be proprioceptd, and this may help to explain our sense of the ineffability of consciousness. Compare Gilbert Ryle in *The Concept of Mind* on the systematic elusiveness of ‘I’ (Ryle 1949, pp. 195-8).

Place has argued that the function of the ‘automatic pilot’, to which he refers as ‘the zombie within’, is to alert consciousness to inputs which it identifies as problematic, while it ignores non-problematic inputs or re-routes them to output without the need for conscious awareness. For this view of consciousness see Place (1999).

Later Objections to the Identity Theory

Mention should here be made of influential criticisms of the identity theory by Saul Kripke and David Chalmers respectively. It will not be possible to discuss them in great detail, partly because of the fact that Kripke's remarks rely on views about modality, possible worlds semantics, and essentialism which some philosophers would want to contest, and because Chalmers' long and rich book would deserve a lengthy answer. Kripke (1980) calls an expression a rigid designator if it refers to the same object in every possible world. Or in counterpart theory it would have an exactly similar counterpart in every possible world. It seems to me that what we count as counterparts is highly contextual. Take the example ‘water is H_20’. In another world, or in a twin earth in our world as Putnam imagines (1975), the stuff found in rivers, lakes, the sea would not be H_20 but XYZ and so would not be water. This is certainly giving preference to real chemistry over folk chemistry, and so far I applaud this. There are therefore contexts in which we say that on twin earth or the envisaged possible world the stuff found in rivers would not be water. Nevertheless there are contexts in which we could envisage a possible world (write a science fiction novel) in which being found in rivers and lakes and the sea, assuaging thirst and sustaining life was more important than the chemical composition and so XYZ would be the counterpart of H_20.

Kripke considers the identity ‘heat = molecular motion’, and holds that this is true in every possible world and so is a necessary truth. Actually the proposition is not quite true, for what about radiant heat? What about heat as defined in classical thermodynamics which is ‘topic neutral’ compared with statistical thermodynamics? Still, suppose that heat has an essence and that it is molecular motion, or at least is in

the context envisaged. Kripke says (1980, p. 151) that when we think that molecular motion might exist in the absence of heat we are confusing this with thinking that the molecular motion might have existed without being *felt* as heat. He asks whether it is analogously possible that if pain is a certain sort of brain process that it has existed without being *felt* as pain. He suggests that the answer is ‘No’. An identity theorist who accepted the account of consciousness as a higher order perception could answer ‘Yes’. We might be aware of a damaged tooth and also of being in an agitation condition (to use Ryle's term for emotional states) without being aware of our awareness. An identity theorist such as Smart would prefer talk of ‘having a pain’ rather than of ‘pain’: pain is not part of the furniture of the world any more than a sense datum or the average plumber is. Kripke concludes (p. 152) that the

> apparent contingency of the connection between the physical state and the corresponding brain state thus cannot be explained by some sort of qualitative analogue as in the case of heat.

Smart would say that there is a sense in which the connection of sensations (sensings) and brain processes is only half contingent. A complete description of the brain state or process (including causes and effects of it) would imply the report of inner experience, but the latter, being topic neutral and so very abstract would not imply the neurological description.

Chalmers (1996) in the course of his exhaustive study of consciousness developed a theory of non-physical qualia which to some extent avoids the worry about nomological danglers. The worry expressed by Smart (1959) is that if there were non-physical qualia there would, most implausibly, have to be laws relating neurophysiological processes to apparently simple properties, and the correlation laws would have to be fundamental, mere danglers from the nomological net (as Feigl called it) of science. Chalmers counters this by supposing that the qualia are not simple but unknown to us are made up of simple proto-qualia, and that the fundamental laws relating these to physical entities relate them to *fundamental* physical entities. His view comes to a rather interesting panpsychism. On the other hand if the topic neutral account is correct, then qualia are no more than points in a multidimensional similarity space, and the overwhelming plausibility will fall on the side of the identity theorist.

On Chalmers' view how are we aware of non-physical qualia? It has been suggested above that this inner awareness is proprioception of the brain by the brain. But what sort of story is possible in the case of awareness of a quale? Chalmers could have some sort of answer to this by means of his principle of coherence according to which the causal neurological story parallels the story of succession of qualia. It is not clear however that this would make us aware of the qualia. The qualia do not seem to be needed in the physiological story of how an antelope avoids a tiger.

People often think that even if a robot could scan its own perceptual processes this would not mean that the robot was conscious. This appeals to our intuitions, but perhaps we could reverse the argument and say that because the robot can be aware of its awareness the robot *is* conscious. I have given reason above to distrust intuitions, but in any case Chalmers comes some of the way in that he toys with the idea that a thermostat has a sort of proto-qualia. The dispute between identity theorists (and physicalists

generally) and Chalmers comes down to our attitude to phenomenology. Certainly walking in a forest, seeing the blue of the sky, the green of the trees, the red of the track, one may find it hard to believe that our qualia are merely points in a multidimensional similarity space. But perhaps that is what *it is like* (to use a phrase that can be distrusted) to be aware of a point in a multidimensional similarity space. One may also, as Place would suggest, be subject to 'the phenomenological fallacy'. At the end of his book Chalmers makes some speculations about the interpretation of quantum mechanics. If they succeed then perhaps we could envisage Chalmers' theory as integrated into physics and him as a physicalist after all. However it could be doubted whether we need to go down to the quantum level to understand consciousness or whether consciousness is relevant to quantum mechanics.

Propositional Attitude Reports

A person can be cognitively related to a proposition in many ways. These cognitive relations might be attributed in sentences like the following:

> Alicia believes that people walked on the Moon.
> Boris knows that people walked on the Moon.
> Carla fears that people walked on the Moon.
> Denzel hopes that people walked on the Moon.

Believing, knowing, fearing and hoping are four different attitudes towards the proposition that people walked on the moon.

Most propositional attitude attributions use a propositional attitude verb that is followed by a *that*-clause, a clause that includes a full sentence expressing a proposition. Attributions of cognitive relations to propositions can also take other kinds of clauses, though: *Alicia wanted to swim, Juan wanted Mary to succeed*, for example. These still attribute propositional attitudes, cognitive relations to an identifiable proposition (*Alicia will swim*, *Mary will succeed*), though the proposition is not so directly expressed.

In this discussion, we will look at some of the attempts to deal with a puzzle about propositional attitude attributions that was posed by Gottlob Frege in [1892]. Developing a semantic theory that deals satisfactorily with propositional attitude attributions has proved to be a very difficult project, and no fully satisfactory theory exists. In what follows, we will explore some of the theories developed to deal with the puzzle and note some of the problems with each theory.

The Fregean Puzzle

The attribution of propositional attitudes raises problems in our attempts to provide a systematic semantics for language. Powerful considerations developed by Gottlob Frege [1892] suggest that words in propositional attitude ascriptions cannot function as they ordinarily do. Frege presents his puzzle as one about the relationship between the cognitive value of expressions and their ordinary reference. Developing a systematic semantics for belief attribution that responds adequately to Frege's puzzle has proved to be very difficult. Every theory seems to have problems that seriously compromise its viability.

The principle of semantic compositionality is fundamental to the Fregean puzzle. We can't learn language by learning each sentence's meaning individually, because mastering a language involves being able to recognize the meanings of an infinite variety of new sentences that we encounter. So our ability to understand language seems to require that we be able to discern the meaning of a sentence on the basis of our knowledge of the meanings of its parts and the way that they are put together. In a word, linguistic meaning must be *compositional* (or at least largely compositional).

The Fregean puzzle can be posed as a question about propositional attitude attributions. (We will use the verb ‘believe’ in the discussion of these puzzles. Similar puzzles arise with all propositional attitudes.) Consider the situation of Lois Lane, who is very familiar with Clark Kent, her fellow employee, and Superman, the hero she most admires, but who does not recognize that ‘Clark Kent’ and ‘Superman’ refer to the same person. We would ordinarily accept these claims about Lois:

(1) Lois believes that Superman is strong.

(2) Lois believes that Clark Kent is not strong.

It would even seem to be true that:

(3) Lois does not believe that Clark Kent is strong.

When we compare the belief attribution (1) with the belief attributions (2) and (3), it seems apparent that the names ‘Superman’ and ‘Clark Kent’ make different semantic contributions to the sentences in which they appear. In particular, it appears that if we replace ‘Superman’ in (1) by the ‘Clark Kent’, it will change a true sentence to a false one.

(4) Lois believes that Clark Kent is strong.

Sentence (4) seems false, even though it results from (1) by replacing one name by another that refers to the same individual. Since the names have the same reference, it seems that something other than the reference of the name must be relevant to the semantic evaluation of the belief attribution.

Without propositional attitude attributions, we might hope for a simpler situation for semantics, in which only the referent of a name is relevant to the evaluation of sentences that contain it.

> (5) Superman is strong.

> (6) Clark Kent is strong.

If (5) is true, then (6) is true as well. Even if Lois and others do not realize it, these sentences must have the same truth-value. So their objective semantics can be the same: each involves a reference to an individual and each predicates the same property of that individual.

However, if we expect semantics to account for the difference in cognitive value of (5) and (6) (Lois accepts one but not the other, and they play different roles in her reasoning), we must recognize a semantic difference in the contribution of the two different names.

So Frege calls our attention to two problems, (i) the problem of the the difference in truth-value of corresponding belief attributions (such as (1) and (4)), and (ii) the problem of the difference in the cognitive significance of sentences composed in the same way of elements with the same reference (such as (5) and (6)). If distinct belief attributions indicate differences in cognitive value of the sentences in their '*that*' -clauses, then these are the same issue, presumably with a single solution.

[For a more complete description of these problems, see the subsection on Frege's Puzzles in the entry on Gottlob Frege.]

Frege's theory

Frege held that correct belief attributions must indicate the way that individuals are represented by the believer (the believer's *mode of presentation* of the referent) and that our use of a referential expression within a belief context refers to a way of representing an object rather than to the expression's ordinary referent. [Frege 1892] When we use 'Superman' and 'Clark' in (1) and (4), we use them to refer to two different ways that Lois has of representing these individuals.

Frege also held that the ordinary sense of an expression --- the way that the expression indicates its referent --- becomes a part of the truth-conditions for a sentence in which the expression occurs, if that expression is used within a belief context.

On the face of it, these are two different theories about terms in belief contexts --- that they refer to the believer's way of representing the object, and that they refer to the ordinary sense. Frege unifies these by holding that the ordinary sense is a way of representing an object.

Thus he can explain why the truth-value of the sentence as a whole can vary in (1) and (4), even though the constituents of the sentences ordinarily make the same contribution to the truth-values of sentences. Belief contexts are not ordinary in that regard, so we must look to the usual sense, not the usual referent, in determining the truth-value of a belief attribution.

Difference in sense also explains the difference in cognitive value of sentences (5) and (6). Though they must have the same truth-value, because the constituents are co-referential, they have different senses, because the names ‘Clark Kent’ and ‘Superman’ have different senses, according to Frege. Though the truth-value depends on the referents of terms, the cognitive value depends on the sense attached to the terms involved in a sentence.

[For a more complete description of Frege's theory, see the subsection on Frege's Theory of Sense and Denotation in the entry on Gottlob Frege.]

Problems for the simple Fregean solution

Frege's solution fails when we try to extend it to all types of propositional clauses that can occur in belief contexts. In referring to individuals, one of our most common ways of doing it is to use demonstratives, such as ‘this’, ‘she’, ‘they’ and similar expressions that can get their reference from an accompanying demonstration. Another common way to refer is by the use of indexicals, such as ‘I’, ‘you’, and ‘now’, that get their reference from features of the context in which they are used. It is dificult to accommodate the use of such terms with a Fregean theory that requires that the mode of presentation is the semantic value of a singular term in a propositional attitude clause. (Kaplan 1977, Perry 1977.) When I point at someone and say:

> (7) Alice believes that he will solve an important problem in physics,

my use of ‘he’ does not indicate anyhing about the way in which Alice represents the individual indicated. Since Frege holds (i) that indicating the sense is indicating the way the believer represents the individual and (ii) that belief attributions indicate the sense, this appears to be a grave problem for his theory. This is perhaps even more evident if I say

> (8) Alice believes that I will solve an important problem in physics.

My use of ‘I’ tells us nothing about how Alice represents me, and it does not refer to anything that we would ordinarily call the *sense* of ‘I’.

Attributions of a common belief to many people also highlight the problems in the Fregean idea that a belief attribution must indicate the way in which the believer represents an individual in belief. If different people have different modes of representation associated with a name, then the belief attributer can't be responsible for the many modes of representation when he ascribes a common belief.

> (9) Many people believe that Tom McKay will solve an important problem in physics.

Someone attributing such a belief cannot be responsible for the many modes of representation that the various believers associate with ‘Tom McKay’. The theory could work in this case only if we could find a sense for ‘Tom McKay’ that does not vary from person to person and that can serve as the mode of presentation of that individual for each person. That seem unlikely. When we use indexicals in such attributions, the problem is perhaps clearest of all:

> (10) Many people believe that I will solve an important problem in physics.

(Similar problems are raised in Schiffer 1992, 507-508.) It seems quite implausible that the truth-conditions for my uterance involve either the many modes of representation that the believers have of me when I assert (10). Only the referent, not its mode of presentation, seems relevant with ordinary uses of indexical expressions like ‘I’, ‘you’, ‘now’, ‘yesterday’ and demonstratives like ‘that’ and ‘he’. [See Perry 1977, 1979].

It appears, then, that our fundamental responsibility in belief attributions is to get the referent right -- i.e., to indicate the individuals the beliefs are about and the properties that the believer attributes to them. The Fregean theory that requires only a reference to the mode of presentation seems wrong or irrelevant in many of our most common sorts of belief attribution. Yet focus on the referent alone seems wrong when we consider the contrast between (1) and (4).

The Russellian theory

Bertrand Russell proposed a view very different from Frege's, arguing that names contribute only their referents to the propositions that contain them. More recent Russellians, (McKay 1980, Salmon 1986 and many subsequent papers, and Soames 1989 and 1995, for example) have followed this much of Russell's view, arguing that the fundamental truth-conditions for belief attributions involve only the objects and properties, not the way those are represented. [Our formulation of the puzzle does not use definite descriptions --- noun phrases of the form *the F*. Russell's own approach to these issues involves, in part, his analysis of definite descriptions. That is explored in the linked discussion of definite descriptions .] According to these Russellians, we are wrong when we say that (1) is true and (4) is false. They are composed in the same way from elements with the same semantic value, and problems like those that we have just considered for the Fregean approach can be a part of arguments for the view that most people's ordinary judgments here are incorrect.

Many Russellians (McKay and Salmon, for example) go on to try to explain why people make those incorrect judgments about truth-values.

There may often be additional responsibilities for indicating the way in which the believer represents the individuals that the beliefs are about, but these go beyond the truth-conditions of the attributions. Any additional responsibilities are pragmatic, not semantic, requirements on the speaker. They may be conditions that a speaker must ordinarily fulfill when making a belief attribution, but they are not part of the semantic content of the attribution.

As we saw in the discussion of the problems in the Fregean approach, indexical cases show clearly that indicating the believer's mode of representation cannot be a general requirement of belief attribution. In addition, we often use names in ways that clearly do not fulfill that requirement. For example, I may say:

> (11) The students believe that John is a great teacher.

even if I know that they refer to him only as ‘Professor Adams’, and none know his first name. In using a name in the attribution, I am not required to use a name that indicates the students' way of representing John in order to say something true.

We sometimes have responsibilities that go beyond just avoiding falsehood. For example, it is true but inappropriate to say ‘John is sober today’ if John is always sober. That sentence is misleading because it suggests a contrast where there is none, though the sentence is true. Confounding pragmatic responsibilities with our responsibility to avoid falsehood can lead people astray concerning the fundamental semantics of belief attribution.

The Russellian must say that (4) is true (given that (1) is), but (4) may be very misleading, depending on the details of the context of attribution. Although Lois believes that Clark Kent is strong, she would never accept the sentence ‘Clark Kent is strong’. She does not accept that sentence, because she does not recognize that it expresses a proposition that she believes. There is a particular individual, who is known both as Clark Kent and as Superman, and she believes that he is strong. (1) and (4) both attribute that belief, but (4) does it in a misleading way, because it uses a sentence that she would not accept. According to this pragmatic explanation of why people go wrong here, the recognition that some utterances of (4) are very misleading and therefore inappropriate produces the feeling that those utterances of (4) are wrong. Though an utterance can feel wrong, we can't trust that feeling to tell us just how it is wrong. On this view, then, (4) is a true but misleading report of Lois's belief. Belief attribution may be guided by a pragmatic rule such as "Do not use a sentence that the believer would not accept, if possible". However, that cannot be a part of the semantics of belief attribution, according to the Russellian.

The Russellian disagrees with the Fregean about what is part of the truth-conditions or the content for belief attributions. This is also a disagreement about the elements of the objects of belief. However, there need not be a very substantive disagreement about what is involved in having a belief. For example, a

Russellian might agree with Frege that in order for Bernie to have a belief about an individual, say Carla, Bernie must have a way of representing Carla (a mode of presentation of Carla). Where they disagree: the Russellian holds that the truth-conditions for the belief sentence

> (12) Bernie believes that Carla is pretty.

do not include anything about Bernie's way of representing Carla, while the Fregean holds that the use of ‘Carla’ in that sentence refers only to that mode of presentation. Still, they can agree that Bernie must have some way of representing Carla for this to be right. They might even agree that a belief attributer should avoid referring to Carla in a way that would mislead us about how Bernie represents her (in the way that (4) is at least misleading about Lois's state of mind). The difference may just be in whether that last responsibility is a part of the truth-conditions or only the appropriateness conditions of the belief attribution.

Problems for Russellian theories

There are several problems and puzzles for this Russellian view, and a thoroughly worked out view will need to respond to all of them.

Pragmatic principles. It seems that the Russellian should have some account of what leads so many people astray in their judgments that (1) and (4) differ in truth-value. If the Russellian wishes to give a pragmatic account of people's ordinary judgments about the truth-value, the Russellian must clearly identify the pragmatic principles that make these incorrect judgments are so pervasive and stubborn.

Asymmetric relations. There are cases that are much less intuitive than even the claim that (4) is true. If names really are inter-substitutable, and if it is true that:

> Lois believes that Superman is stronger than Clark Kent.

then these must also be true:

> Lois believes that Superman is stronger than Superman.

> Lois believes that Clark Kent is stronger than Superman.

Can it really be that these are true, and that the typical strong feeling that they are false is really a feeling of pragmatic inappropriateness? Must Lois also believe that Superman is stronger than himself, or can we differentiate this from the previous claims? (See Salmon 1992, McKay 1991)

Negation. According to Russellians, the belief attribution:

(1) Lois believes that Superman is strong.

ordinarily conveys the meaning that Lois believes of that individual that he is strong. However, according to some, it is also a conversational implicature of that sentence that Lois would accept 'Superman is strong', and an ordinary use of the sentence conveys that too. On the other hand

(4) Lois believes that Clark Kent is strong.

is also true, but it implicates something false, and that leads to our judgment that the sentence is inappropriate or even false.

What about negation?

(3) Lois does not believe that Clark Kent is strong.

This is a false sentence, according to the Russellian, but it would ordinarily be judged true. In addition, it would ordinarily convey the idea that there is a particular way of representing the individual (as *Clark Kent*) such that Lois does not represent him as strong in association with that mode of representation. How does a use of a false sentence like this produce such judgments? The Russellian who wishes to provide a pragmatics-based account of how people's ordinary judgments go astray needs to explain this, and it is not so evident how to do that. (See Recanati, 1993, pp. 341-345)

Mixed theories

Mark Richard [1990], Crimmins and Perry [1989], Crimmins [1992], and many others have interpreted belief attributions in a way that holds us responsible for both the Russellian propositional content and for the believer's way of representing the content. The standards for getting the mode of representation right vary with context, and tend to fade to nothing in cases invoving attributions like (9) and (10). However, they do more than just hold us responsible --- they agree with Frege that a belief attributer will say something false if the singular term in the attribution does not appropriately represent the believer's way of representing the object. They differ from Frege in that they also regard the Russellian proposition as a part of the content of the belief attributed. (Some views of this kind have been called "hidden-indexical theories," because they make reference to a type of mode of representation without having any word that explicitly refers to that does just that job. See Schiffer 1992, p. 503.)

This can provide for results that many people find satisfying. For example, on this kind of view:

(13) Lois believes that Superman is strong

is true in ordinary contexts; but

(14) Lois believes that Clark Kent is strong

is false in ordinary contexts. On the other hand, pointing to Clark Kent naked in the sauna and saying

(15) Lois believes that he is strong

one may speak truly or falsely, depending on a variety of contextual factors. (Whether the audience knows about the Superman disguise, what kind of information about Lois is required in the context, etc..)

Objections of Bach [1993], Braun [1991], Rieber [1995], Schiffer [1992, 1994], Saul [1992, 1997] and Soames [1995] have raised difficulties for such views. The principal problem is how to incorporate the mode of presentation.

(A) If the mode of presentation must be referred to (as Frege required), then we get incorrect results concerning the possibility of belief attribution, because our attributions are too particular. For example, we often wish to say that distinct individuals share a belief even though they have different modes of presentation of the individuals the belief is about. Lois Lane and Lex Luthor share the belief that Superman flies, even though they have somewhat different modes of presentation for Superman. This is a problem that also arose for the pure Fregean theory.

(B) If the truth of a belief attribution requires only that the mode of presentation is of some general sort, without a reference to a particular mode of presentation, still that cannot be a part of the content of the belief attribution. When we attribute beliefs, we are not attributing acceptance of a claim that there are modes of presentation of a certain sort. In saying that Lois Lane believes that Superman flies, a speaker does not take on a commitment to the metaphysical claim that there exist modes of presentation. Belief attributions just don't seem to be making the kind of claim that such a view would require.

(C) Could the mode of presentation be a part of the truth-conditions without being a part of the content? Could it be like the situation with indexicals, where, for example it is part of the truth-conditions for an utterance of ‘You are bald’ that the addressee of the utterance is bald, but it is not a part of the content of that utterance that there is an addressee or that that there are utterances? That doesn't seem to work. If I point to Smith and say

(16) You are bald.

it is never a part of the content of the utterance that there is an addressee of my utterance, even though there must be an addressee if that sentence is to succeed in expressing the intended meaning. Other utterances, by other speakers (‘He is bald’, ‘I am bald’ and ‘Smith is bald’), could have the same content, (and they clearly do not have as part of their content the claim that there are utterances and addressees of those utterances). When I say

(1) Lois believes that Superman is strong

the analogue would be to say that it is never a part of the content of my utterance that Lois represents this individual in a certain way. That, though, is the Russellian theory, not the view we are currently considering.

Ambiguity theories

Ambiguity theories share many features of the mixed theories just described. Consideration of such views is useful, even if we find the views ultimately unsatisfactory.

First I want to consider the view that ‘believe’ is ambiguous. In one use, the verb is used to relate us to a Fregean proposition, a way of representing the world. On the other use, it relates us to a Russellian proposition or state of affairs, something that has individuals, properties, relations, etc. as contituents.

When there is an ambiguity, usually the most useful thing is to introduce two terms, one for each of the two different meanings involved. Thus, for a time, I will introduce ‘accept’ and ‘doxate’. Since it is natural to say that we ‘accept’ sentences and other sentence-like representations, let us extend this usage to say that we ‘accept’ Fregean thoughts, which include modes of presentation of individuals. By contrast, let us say that we ‘doxate’ Russellian propositions. For example, using quoted sentences to refer to Fregean thoughts:

(17) Lois Lane accepts ‘Superman is strong’.

(18) Lois does not accept ‘Superman is not strong’.

(19) Lois accepts ‘Clark Kent is not strong’.

(20) Lois does not accept ‘Clark Kent is strong’.

(21) Lois doxates the Russelian proposition that Clark Kent is strong. (Because of (1).)

(22) Lois doxates the Russellian proposition that Clark Kent is not strong. (Because of (3).)

It is natural to hold that there are two standards of consistency. One applies to sentences, according to which the sentences ‘Superman is strong’ and ‘Clark Kent is not strong’ are consistent. Nothing in the form of the sentences rules out the possibility that both are true. There is nothing about the use of negation that would create inconsistency between the quoted sentences within (17) and (19), in the way that it does for the quoted sentences within (17) and (18). The Russellian propositions that the quoted sentences in (17) and (19) express, on the other hand, are propositionally inconsistent. They cannot both be true. That cannot be seen just by inspecting the sentences that express those propostions; one must also know the co-reference relations among the terms used. Thus the sentences that Lois accepts are

consistent (by the first standard), but the Russellian propositions that she doxates in virtue of accepting those sentences (in the world we imagine for her story) are inconsistent. Because ‘Superman’ and ‘Clark Kent’ refer to the same individual, the two sentences that Lois accepts express Russellian propositions that cannot both be true.

The puzzles that arise when we consider the question of whether Lois has consistent *beliefs* can at least be addressed if we instead ask about what she accepts and about what she doxates, for use of these two terms helps to make it clear that two standards of consistency apply. One standard applies to the form of the sentences accepted, without taking account of co-reference relations among terms, and the other considers the content of terms and applies to Russellian objects of doxation. The sentences she accepts are consistent by the first standard -- they are the kinds of sentences that could be used to express propositions that are both true, and Lois has no reason to believe that that is not the case in the current situation. She is wrong, however, because these sentences express propositions that cannot both be true. By identifying an ambiguity, we provide resources for an answer to the vexing puzzles.

Some philosophers have connected the *de dicto -de re* distinction with such an ambiguity in ‘believe’. That view, though, has many difficulties, and the *de dicto -de re* terminology is used in other ways, to mark distinctions among beliefs or distinctions among belief attributions. Rather than trying to sort out different interpretations of that terminology, though, let's stick with the invented disambiguating verbs ‘accept’ and ‘doxate’, briefly, for heuristic purposes. [Interested readers may with to pursue a more in-depth discussion of the de re/de dicto distinction.]

The ambiguity theory of belief attribution has a certain appeal. In ordinary cases of belief attribution, the sentence attributing the belief can do both things at once. It can indicate the Russellian proposition that is the object of doxation, and it can indicate the sentence (or sentence-like representation) that is accepted by the believer. (When I say "Alice believes that George Eliot was a great novelist", I indicate the way that Alice represents the novelist and the individual her belief is about.) Those are paradigm cases of the use of ‘believe’. Treating ‘believe’ as univocal, however, would leave us with a problem in cases like Lois's, where we need to say different things about acceptance and doxation. (For example, regarding what she accepts, she is epistemically in the clear. Her view meets the appropriate standard of consistency. However, the propositions that she doxates are inconsistent. And she rejects certain sentences that express propositions that she doxates (such as (2) and (4)).)

The situation with ‘believe’, on this view, is something like the situation with ‘is heavier than’ as ordinarily used. That expression could be talking about greater weight or greater mass. Ordinarily it doesn't matter; we can express both propositions at the same time, since for the most part their truth-conditions vary together. (We can have *polysemy*, where the two meanings are simultaneously expressed, not just ambiguity.) But if we are comparing objects that are on different planets, or even at very different elevations on this planet, then we will have to make it clear whether we are concerned with mass or weight. Similarly, we can often indicate what is accepted and what is doxated, but in some situations we cannot do both, and so we must make it clear which we are concerned with. We can make it clear by employing the language of acceptance and doxation instead of the language of belief.

This first ambiguity view, then, just claims that 'believe' is ambiguous (in the way that 'is heavier than' is ambiguous) and that the ambiguity can be resolved by recognizing the two different things that are ordinarily captured in successful belief attributions. The strategy suggested here is the ordinary one for dealing with an ambiguity; we find or invent two terms and stipulate which will go with each of the meanings. Thus we might firmly stipulate that 'is heavier than' will be associated with weight comparisons and introduce 'has more mass than' for comparisons of mass.

Ultimately such a strategy will not work for 'believe' however, because the situation is more complicated. Some belief attributions involve sentences that use one singular term in a purely referential way but use other terms in a way that seems to require getting the mode of representation right. For example, it could bethat Lois spots a man walking in the corridor, and makes a height judgment that leads her to say two things:

> (23) He is taller than Superman.

> (24) He is not taller than Clark Kent.

I might recognize the man in question as Rudy Sanchez, someone known to me and the people I am speaking to, but unknown to Lois (outside of the brief sighting in the corridor). I can then make these attributions:

> (25) Lois believes that Rudy Sanchez is taller than Superman.

> (26) Lois believes that Rudy Sanchez is not taller than Clark Kent.

Is this acceptance or doxation? It seems that it must be both, because the name 'Rudy Sanchez' is not being used to indicate Lois's mode of representation of the individual, but the names 'Superman' and 'Clark Kent' are (according to a theorist who might find this ambiguity theory attractive). With the following pair, where Rudy Sanchez is the speaker, the situation is perhaps even clearer.

> (27) Lois believes that I am taller than Superman.

> (28) Lois believes that I am not taller than Clark Kent.

This cannot be an ambiguity located in the verb 'believe' after all. Our intuitions support the idea that there are two different kinds of uses of singular terms (*de re* and *de dicto*) in belief attributions, but that will not divide belief attributions into the *de re* and *de dicto*, because names being used in different ways can occur in a single attribution.

Edward N. Zalta has suggested a different approach that involves ambiguity in belief attributions. [Zalta 1983]

Non-compositional accounts

Our ability to understand the sentences of a language is open-ended. Our semantic theory must provide for that fact, and this is the basis for holding firm to the idea of semantic compositionality. We can understand an infinity of novel sentences, based on our understanding of words and how they are put together. Any account that breaches the principle of compositionality must provide an alternative account of how this understanding is possible.

Mark Crimmins [Crimmins 1998] has recently suggested an approach that gives up on compositionality, in at least a limited way. The truth conditions of complex expressions are not determined simply by the meanings of their parts and how they are composed. Instead, in some cases, the truth-value of a sentence is determined by the truth-value it would have in a certain fictional situation. This is based on a theory of fiction that says, for example, that

> Santa Claus wears a red suit

is true as we usually use it, because it is true in a certain fictional situation that serves as the background for the utterance.

Applied to belief attributions, we imagine a certain pretense that goes with sentences like these:

> (1) Lois believes that Superman is strong.
>
> (2) Lois believes that Clark Kent is not strong.

The pretense is that there are people, Superman and Clark Kent, corresponding to Lois's modes of presentation, and associated with our use of ‘Superman’ and ‘Clark Kent’. The pretense makes the differing attributions possible, even though ‘Superman’ and ‘Clark Kent’ both refer to the same person. At the same time, in order for Lois's first belief to be true and the second false, we must keep the terms firmly attached to that person as the object of his belief. Thus, this theory gives us the dual interpretation of names required in the mixed theories of belief attribution discussed earlier. It supplements the theory by providing a specific, non-compositional account of the truth-conditions for such sentences. Although this account is non-compositional, it is clear how we can understand new belief attributions, by applying our ordinary compositional semantics to interpret sentences with respect to non-actual situations. (Note: in using the Superman example throughout our discussion, we have already taken advantage of our ability to do engage in some pretense --- the pretense that Clark and Lois exist. Perhaps this is similar.)

This account provides no evident way to avoid problems like those that come up for the mixed theories, however. If we are engaging in pretenses that correspond to particular people's modes of presentation when we use names, then we cannot take agreement to be sharing a belief. Different people may share a belief even though they represent the object of belief in different ways. If many people know that ‘Clark

Kent' and 'Superman' are co-referential and many don't know that, then we cannot attribute common beliefs, like "Almost everyone believes that Superman is the most important citizen of Metropolis." [See Crimmins 1998]

William Taschek has also developed a theory that he says is non-compositional, in another recent attempt to deal with the Fregean puzzles. [Taschek 1998]

Concluding note

Ultimately, a response to Frege's puzzle must fit with a broader theory of human interaction. People communicate their beliefs, they agree when they share a belief, and beliefs play a role in motivating and explaining action. Any account of belief attributions must say how these attributions can accurately reflect these many roles.

Content Last Modified: September 15, 2000

This Catalog was compiled initially by cross-checking the Bibliographies in the following works: Bynum [1972], Beaney [1997], Hermes [1969], and Angelelli [1967]. Sources were checked whenever possible and inconsistencies and omissions were rectified. The publication history of each English translation was developed. Please notify the author if you find any errors or missing items. (No citations to Frege's letters are included. Frege's correspondence may be found in Gabriel *et al.* [1976] and Janik [1989], many of which were translated in Gabriel *et al.* [1980], Kluge [1971], and Woodward [1967].)

Contents

Chronological Catalog of Frege's Work

• [**1873**] *Über eine geometrische Darstellung der imaginären Gebilde in der Ebene*, Inaugural-Dissertation der Philosophischen Fakultät zu Göttingen zur Erlangung der Doktorwürde, Jena: A. Neuenhann, 1873; reprinted in Angelelli [1967] (pp. 1-49)

> *On a Geometrical Representation of the Imaginary Forms in the Plane*, Doctoral Dissertation, School of Philosophy, U. Göttingen; translation by H. Kaal in McGuinness [1984] (pp. 1-55)

• [**1874a**] *Rechnungsmethoden, die sich auf eine Erweiterung des Grössenbegriffes gründen*, Dissertation zur Erlangung der Venia Docendi bei der Philosophischen Fakultät in Jena, Jena: Friedrich Frommann, 1874; reprinted in Angelelli [1967] (pp. 50-84)

> *Methods of Calculation based on an Extension of the Concept of Quantity*, Dissertation for the Venia Docendi (Habilitationsschrift) in the School of Philosophy of Jena; translation by H. Kaal in McGuinness [1984] (pp. 56-92)

• [**1874b**] 'Rezension von: H. Seeger, *Die Elemente der Arithmetik*', *Jenaer Literaturzeitung* **1**/46 (1874): 722; reprinted in Angelelli [1967] (pp. 85-86)

> 'Review of H. Seeger, *The Elements of Arithmetic*'; translation by H. Kaal in McGuinness [1984] (pp. 93-4)

• [**1877a**] 'Rezension von: A. v. Gall and E. Winter, *Die analytische Geometrie des Punktes und der Geraden und ihre Anwendung auf Aufgaben*', *Jenaer Literaturzeitung* **4**/9 (1877): 133-134; reprinted in Angelelli [1967] (pp. 87-88)

> Review of A. v. Gall and E. Winter, *Analytic Geometry of the Point and the Line and its Application to Problems*; translation by H. Kaal in McGuinness [1984] (pp. 95-97)

• [**1877b**] 'Review of J. Thomae, *Sammlung von Formeln welche bei Anwendung der elliptischen und Rosenhainschen Funktionen gebraucht werden*', *Jenaer Literaturzeitung* **4**/30 (1877), p. 472; reprinted in Angelelli [1967] (p. 89)

> 'Review of J. Thomae, *Collection of Formulae used in the Application of Elliptical and Rosenhain Functions*'; translation by H. Kaal in McGuinness [1984] (p. 98)

• [**1878**] 'Über eine Weise, die Gestalt eines Dreiecks als komplexe Grösse aufzufassen', Vortrag, gehalten in in der Sitzung vom 8. Februar 1878, der Jenaischen Gesellschaft für Medizin und Naturwissenschaft, in *Jenaische Zeitschrift für Naturwissenschft* **12**/Supplement (1878) (= Sitzungsberichte der Jenaischen Gesellschaft für Medizin und Naturwissenschaft für das Jahr 1878), p. xviii; reprinted in Angelelli [1967] (pp. 90-91)

'On a Way of Conceiving the Shape of a Triangle as a Complex Quantity' (Lecture at the February 8, 1878 meeting of Jena's Society for Medicine and Natural Science); translation by H. Kaal in McGuinness [1984] (pp. 99-100)

• [**1879**] *Begriffsschrift, eine der arithmetischen nachgebildete Formelsprache des reinen Denkens*, Halle a. S.: Louis Nebert, 1879; reprinted in Angelelli [1964] (pp. ix-xvi, 1-88)

Concept Script, a formal language of pure thought modelled upon that of arithmetic;

- Complete translation by S. Bauer-Mengelberg in van Heijenoort [1967] (pp. 1-82)
- Complete translation by T. Bynum in Bynum [1972] (pp. 101-203)
- Partial translation (§§1-12) by P. Geach in Geach and Black [1980] (pp. 1-20)
- Partial translation (§§1-12) by M. Beaney in Beaney [1997] (pp. 47-78)

• [**1879b**] 'Anwendungen der Begriffsschrift', Vortrag, gehalten in der Sitzung vom 24. Januar 1879 der Jenaischen Gesellschaft für Medizin und Naturwissenschaft, in *Jenaische Zeitschrift für Naturwissenschaft* **13**/Supplement II (1879) (= Sitzungsberichte der Jenaischen Gesellschaft für Medizin und Naturwissenschaft für das Jahr 1879), pp. 29-33; reprinted in Angelelli [1964] (pp. 89-93)

'Applications of the Concept Script' (Lecture at the January 24, 1879 meeting of Jena's Society for Medicine and Natural Science); translation by T. Bynum in Bynum [1972] (pp. 204-8)

• [1879?] (Logik), originally unpublished; recently published in Hermes *et al.* [1969] (pp. 1-8)

(Logic), (originally unpublished), translation by Long and White in Hermes *et al.* [1979] (pp. 1-9)

• [**1880**] 'Rezension von: Hoppe, *Lehrbuch der analytischen Geometrie I*', *Deutsche Literaturzeitung*, **1** (1880): columns 210-211; reprinted in Angelelli [1967] (pp. 92-93)

'Review of Hoppe, *Textbook of Analytic Geometry I*'; translation by H. Kaal in McGuinness [1984] (pp. 101-102)

• [1880?] 'Booles rechnende Logik und die Begriffsschrift', originally unpublished; recently published in Hermes *et al.* [1969] (pp. 9-52)

'Boole's Logical Calculus and the Concept Script', (originally unpublished), translation by Long and White in Hermes *et al.* [1979] (pp. 9-46)

• [**1881**] ‘Über den Briefwechsel Leibnizens und Huygens mit Papin’, Vortrag, gehalten in der Sitzung vom 15. Juli 1881 der Jenaischen Gesellschaft für Medizin und Naturwissenschaft, in *Jenaische Zeitschrift für Naturwissenschaft*, **15**/Supplement (1881-1882) (= Sitzungsberichte der Jenaischen Gesellschaft für Medizin und Naturwissenschaft für das Jahr 1881), pp. 29-32; reprinted in Angelelli [1964] (pp. 93-96)

> ‘On Leibniz’s and Huygens’ Letter Exchange with Papin’ (Lecture at the July 15, 1881 meeting of Jena’s Society for Medicine and Natural Science); no English translation available.

• [**1882a**] ‘Über die wissenschaftliche Berechtigung einer Begriffsschrift’, *Zeitschrift für Philosophie und philosophische Kritik*, **81** (1882), pp. 48-56; reprinted in Angelelli [1964] (pp. 106-114) and in Patzig [1962] (pp. 91-97)

> ‘On the Scientific Justification of a Concept Script’
>
> - Translation by J. Bartlett in Bartlett [1964]
> - Translation by T. Bynum in Bynum [1972] (pp. 83-89)

• [**1882b**] ‘Über den Zweck der Begriffsschrift’, Vortrag, gehalten in der Sitzung vom 27. Januar 1882 der Jenaischen Gesellschaft für Medizin und Naturwissenschaft, *Jenaische Zeitschrift für Naturwissenschaft*, **16**/Supplement (1882/1883) (= Sitzungsberichte der Jenaischen Gesellschaft für Medizin und Naturwissenschaft für das Jahr 1882), pp. 1-10 reprinted in Angelelli [1964] (pp. 97-106)

> ‘On the Purpose of Concept Script (Lecture at the January 27, 1882 meeting of Jena’s Society for Medicine and Natural Science)
>
> - Translation by V. Dudman in Dudman [1968]
> - Translation by T. Bynum in Bynum [1972] (pp. 90-100)

• [1882c] ‘Booles logische Formelsprache und meine Begriffsschrift’, originally unpublished; recently published in Hermes *et al.* [1969] (pp. 53-59)

> ‘Boole’s Logical Formula Language and my Concept Script’, (originally unpublished), translation by Long and White in Hermes *et al.* [1979] (pp. 47-52)

• [1882d?] (17 Kernsätze zur Logik), originally unpublished; recently published in Hermes *et al.* [1969] (pp. 189-190) [Note: This piece was thought to have been written in 1876, but research by G. Gabriel suggests the date of 1882.]

> (17 Key Sentences on Logic), (originally unpublished), translation by Long and White in Hermes *et al.* [1979] (pp. 174-175)

• [**1883**] ‘Geometrie der Punktpaare in der Ebene’, Vortrag, gehalten in der Sitzung vom 2. November 1883 der Jenaischen Gesellschaft für Medizin und Naturwissenschaft, in *Jenaische Zeitschrift für Naturwissenschaft*, **17**/Supplement (1884) (= Sitzungberichte der Jenaischen Gesellschaft für Medizin und Naturwissenschaft für das Jahr 1883), pp. 98-102; reprinted in Angelelli [1967] (pp. 94-98)

‘Geometry of Pairs of Points in the Plane’ (Lecture at the November 2, 1883 meeting of Jena’s Society for Medicine and Natural Science); translation by H. Kaal in McGuinness [1984] pp. 103-107

• [1883?] (Dialog mit Pünjer über Existenz), originally unpublished; recently published in Hermes *et al.* [1969] (pp. 60-75)

(Dialogue with Pünjer on Existence), (originally unpublished), translation by Long and White in Hermes *et al.* [1979] (pp. 53-67)

• [**1884**] *Die Grundlagen der Arithmetik: eine logisch-mathematische Untersuchung über den Begriff der Zahl*, Breslau: W. Koebner, 1884; reprinted Breslau: M. & H. Marcus, 1934; reprinted Darmstadt: Wissenschaftliche Buchgesellschaft and Hildesheim: Olms, 1961; reprinted in Thiel [1986]

The Foundations of Arithmetic: A logico-mathematical enquiry into the concept of number

- Complete translation by J. L. Austin in Austin [1974] (complete) and (pp. v-viii and §§21-27) in Kennick and Lazerowitz [1966] (pp. 67-74)
- Partial translation (§§55-91, §§106-109) by M. Mahoney in Benacerraf and Putnam [1983] (pp. 130-159)/[1964] (pp. 85-112)
- Partial translation (Introduction, §§1-4, §§45-69, §§87-91, §§104-9) by M. Beaney in Beaney [1997] (pp. 84-129)

• [**1885a**] ‘Rezension von: H. Cohen, *Das Prinzip der Infinitesimal-Methode und seine Geschichte*’, *Zeitschrift für Philosophie und philosophische Kritik* **87** (1885), pp. 324-329; reprinted in Angelelli [1967] (pp. 99-102)

‘Review of H. Cohen, *The Principle of the Method of Infinitesimals and its History*’; translation by H. Kaal in McGuinness [1984] (pp. 108-111)

• [**1885b**] ‘Über formale Theorien der Arithmetik’, Vortrag, gehalten in der Sitzung vom 17. July 1885 der Jenaischen Gesellschaft für Medizin und Naturwissenschaft, in *Jenaische Zeitschrift für Naturwissenschaft*, **19**/Supplement II (1886) (= Sitzungberichte der Jenaischen Gesellschaft für Medizin und Naturwissenschaft für das Jahr 1885), pp. 94-104; reprinted in Angelelli [1967] (pp. 103-111)

‘On Formal Theories of Arithmetic’ (Lecture at the July 17, 1885 meeting of Jena’s Society for Medicine and Natural Science); translation by E.-H. W. Kluge in Kluge [1971] (pp. 141-153) and in McGuinness [1984] (pp. 112-121)

• [**1885c**] ‘Erwiderung’ (auf Cantors Rezension der *Grundlagen der Arithmetik*), *Deutsche Literaturzeitung*, **6**/28 (1885), column 1030; reprinted in Angelelli [1967] (p. 112)

'Reply', translation by H. Kaal in McGuinness [1984] (p. 122)

[Note: This is a brief reply to Cantor, G., 'Rezension der *Grundlagen der Arithmetik*', which appeared in *Deutsche Literaturzeitung*, **6**/20 (1885), columns 728-729.]

• [1890-2] (Entwurf zu einer Besprechung von Cantors Gesammelten Abhandlungen zur Lehre vom Transfiniten), originally unpublished; recently published in Hermes *et al.* [1969] (pp. 76-80)

(Draft of a review of Cantor's book *Contributions to the Theory of the Transfinite: Collected Articles from Zeitschrift für Philosophie und philosophische Kritik*), (originally unpublished), translation by Long and White in Hermes *et al.* [1979] (pp. 68-71)

• [**1891a**] 'Funktion und Begriff', Vortrag, gehalten in der Sitzung vom 9. Januar 1891 der Jenaischen Gesellschaft für Medizin und Naturwissenschaft, Jena: Hermann Pohle, 1891; reprinted in Angelelli [1967] (pp. 125-142) and in Patzig [1962] (pp. 17-39)

'Function and Concept' (Lecture at the January 9, 1891 meeting of Jena's Society for Medicine and Natural Science); translation by P. Geach in Geach and Black [1980] (pp. 21-41), McGuinness [1984] (pp. 137-156), and (with minor revisions) in Beaney [1997] (pp. 130-148)

• [**1891b**] 'Über das Trägheitsgesetz', *Zeitschrift für Philosophie und philosophische Kritik*, **98** (1891): 145-161; reprinted in Angelelli [1967] (pp. 113-124)

'On the Law of Inertia'

- Translation by H. Kaal in McGuinness [1984] (pp. 123-136)
- Translation by R. Rand in Rand [1961]

• [1891?a] 'Über den Begriff der Zahl: 1. Eine kritische Auseinandersetzung mit Biermann', originally unpublished; recently published in Hermes *et al.* [1969] (pp. 81-95)

'On the Concept of Number: 1. A Criticism of Biermann', (originally unpublished), translation by Long and White in Hermes *et al.* [1979] (pp. 72-86)

• [1891?b] 'Über den Begriff der Zahl: 2. Eine kritische Auseinandersetzung mit Kerry', originally unpublished draft of Frege [1892b]; recently published in Hermes *et al.* [1969] (pp. 96-127)

'On the Concept of Number: 2. A Criticism of Kerry', originally unpublished draft of Frege [1892b]; translation by Long and White in Hermes *et al.* [1979] (pp. 87-117)

• [**1892a**] 'Über Sinn und Bedeutung', in *Zeitschrift für Philosophie und philosophische Kritik*, **100** (1892), pp. 25-50; reprinted in Angelelli [1967] (pp. 143-162) and in Patzig [1962] (pp. 40-65)

'On Sense and Meaning'

- Translation by M. Black in Black [1948], Geach and Black [1980] (pp. 56-78), McGuinness [1984] (pp. 157-177), Martinich [1985] (pp. 200-212), and (with minor revisions) Beaney [1997] (pp. 151-171)
- Translation by H. Feigl in Feigl and Sellars [1949] (pp. 85-102), in Nagel and Brandt [1965] (pp. 69-78), and in Martinich [1996] (pp. 186-198)

• [**1892b**] 'Über Begriff und Gegenstand', in *Vierteljahresschrift für wissenschaftliche Philosophie*, **16** (1892): 192-205; reprinted in Angelelli [1967] (pp. 167-178) and in Patzig [1962] (pp. 66-80)

'On Concept and Object', translation by P. Geach in Geach [1951], Geach and Black [1980] (pp. 42-55), Hermes *et al.* [1979] (pp. 87-117), McGuinness [1984] (pp. 182-194), and (with minor revisions) in Beaney [1997] (pp. 181-193)

• [**1892c**] 'Rezension von: G. Cantor, *Zur Lehre vom Transfiniten: Gesammelte Abhandlungen aus der Zeitschrift für Philosophie und philosophische Kritik*', **100** (1892), pp. 269-272; reprinted in Angelelli [1967] (pp. 163-166)

'Review of Georg Cantor, *Contributions to the Theory of the Transfinite: Collected Articles from Zeitschrift für Philosophie und philosophische Kritik*', translation by H. Kaal in McGuinness [1984] (pp. 178-181)

• [1892-5] (Ausführungen über Sinn und Bedeutung), originally unpublished; recently published in Hermes *et al.* [1969] (pp. 128-136)

(Comments on Sense and Meaning), (originally unpublished), translation by Long and White in Hermes *et al.* [1979] (pp. 118-125)

• [**1893**] *Grundgesetze der Arithmetik*, Jena: Verlag Hermann Pohle, Band I; reprinted Hildesheim: Olms, 1962; reprinted in Thiel [1998]

The Fundamental Laws of Arithmetic: I

- Partial translation (Preface, Introduction, §§1-52) by M. Furth in Furth [1964]
- Partial translation (almost all of the Preface, Introduction, §§1-7) by Stachelroth and Jourdain in Stachelroth and Jourdain [1915-1917], and (Preface abridged further) in Geach and Black [1980] (pp. 137-159), and (only small part of the Preface) in Copi and Gould [1964] (pp. 205-210)

- Partial translation (most of the Preface, Introduction, §§1-6, parts of §§26-33) by M. Beaney in Beaney [1997] (pp. 194-223)

• [**1894**] 'Rezension von: E. Husserl, *Philosophie der Arithmetik I*', in *Zeitschrift für Philosophie und philosophische Kritik*, **103** (1894), pp. 313-332; reprinted in Angelelli [1967] (pp. 179-192)

'Review of E. Husserl's *Philosophy of Arithmetic I*'

- Translation by H. Kaal in McGuinness [1984] (pp. 195-209) (complete) and in Beaney [1997] (pp. 224-226) (partial)
- Partial translation by P. Geach in Geach and Black [1980] (pp. 79-85)

• [**1895a**] 'Kritische Beleuchtung einiger Punkte in E. Schröders *Vorlesungen über die Algebra der Logik*, in *Archiv für systematische Philosophie*, **I** (1895): 433-456; reprinted in Angelelli [1967] (pp. 193-210) and in Patzig [1966] (pp. 92-112)

'A Critical Elucidation of Some Points in E. Schröder, *Lectures on the Algebra of Logic*', translation by P. Geach in Geach and Black [1980] (pp. 86-106) and in McGuinness [1984] (pp. 210-228)

• [**1895b**] 'Le Nombre Entier', *Revue de Métaphysique et de Morale* **3** (1895) pp. 73-78; reprinted in Angelelli [1967] (pp. 211-219)

'Whole Numbers', (the original is in French); translation by V. H. Dudman in Dudman [1970], and in McGuinness [1984] (pp. 229-233)

• [**1896a**] 'Lettera del Sig. G. Frege all'Editore', *Rivista di Matematica*, **6** (1896-9): 53-59; reprinted in Angelelli [1967] (pp. 234-239) and in Gabriel *et al.* [1976] (pp. 181-186)

'Letter to the Editor' (original in German); translation by H. Kaal in Gabriel *et al.* [1980] (pp. 112-118). [Note: The Editor of the *Rivista di Matematica* was G. Peano.]

• [**1897**] 'Über die Begriffsschrift des Herrn Peano und meine eigene', Vortrag, gehalten in der ausserordenlichen Sitzung vom 6. Juli 1896, *Berichte über die Verhandlungen der Königlich Sächsischen Gesellschaft der Wissenschaften zu Leipzig: Mathematisch-physische Klasse*, **48** (1897): 361-378; reprinted in Angelelli [1967] (pp. 220-233)

'On Mr. Peano's Concept Script and My Own', Lecture at the special July 6, 1896 meeting of Leipzig's Science Society; translation by V. H. Dudman in Dudman [1969] and in McGuinness [1984] (pp. 234-248)

• [1897] 'Logik', originally unpublished; recently published in Hermes *et al.* [1969] (pp. 137-163)

'Logic', (originally unpublished), translation by P. Long and R. White in Hermes *et al.* [1979] (pp. 126-151) and (the first two sections reappear with minor revisions) in Beaney [1997] (pp. 227-250)

Supplement to Propositional Attitude Reports

Definite Descriptions

Russell's reply to Frege employed his theory of definite descriptions as a part of the reply. See Bertrand Russell. According to this theory, sentences with definite descriptions, phrases of the form ‘the F’, are to be analyzed in a way that indicates that the definite description is not a unitary part of the sentence. In particular,

> The man wearing a beret is bald.

is to be understood as equivalent to the following:

> Some man is wearing a beret, and at most one man is wearing a beret, and every man wearing a beret is bald.

This facilitates a response to versions of the Fregean puzzle involving definite descriptions. More complex sentences with definite descriptions will be ambiguous. Applying the account of definite descriptions to belief sentences, we get these results:

> George IV believed that the person who wrote *Waverly* was famous.
>
> **A version**: George IV believed that some person wrote *Waverly*, at most one person wrote *Waverly*, and every person who wrote *Waverly* is famous.
>
> **B version**: Some person wrote *Waverly*, at most one person wrote *Waverly*, and every person who wrote *Waverly* is an *x* such that George IV believed that *x* was famous.

If George IV was in doubt about the identity of the author of *Waverly*, wondering whether it was Sir Walter Scott or someone else, then the **A version** would be true, but the **B version** could be false. George IV would be engaged in a general belief, without specific knowledge of any person's writing of *Waverly*, and that is captured by the **A version**.

Retaining the definite description, we could distinguish the two readings of the sentence as follows:

> **A version**: George believed that this was true: the author of *Waverly* was famous.

> **B version**: The author of *Waverly* was an individual *x* such that George IV believed that *x* was famous.

This is a distinction in the *scope* of the definite description. In the **A version**, the definite description has small scope, within the propositional object clause of the belief ascription. In the **B version**, the definite description has large scope, in effect "picking out" an individual and then ascribing to George IV a belief about that individual. The **A version** can also be identified as a *de dicto* ascription of belief (relating him to a *dictum*, a complete proposition), whereas the **B version** is a *de re* ascription of belief (relating him to an individual, a *res*, that his belief is about). (See the discussion of *the de re/de dicto distinction*.)

Frege's puzzle concerns questions like the following:

> How could this be true: *Albert believes that the Venus rises in the morning*, though this is not true: *Albert believes that the evening star rises in the morning*?

Since Venus is the evening star, why does substitution of one name for the other affect the correctness of the ascription? The russellian answer lies in recognizing the ambiguity in the second sentence, which involves a definite description.

> Albert believes that the evening star rises in the morning.
>
> **A version**: Albert believes that this is true: the evening star rises in the morning.
>
> **B version**: The evening star is an individual *x* such that Albert believes that *x* rises in the morning**.**

The falsity of the **A version** does not conflict with Albert's belief about Venus, that it rises in the morning, since the **A version** ascribes a belief in a complete dictum and does not relate Albert to an individual. The difference in truth-value between *Albert believes that the Venus rises in the morning* and *Albert believes that the evening star rises in the morning* is no longer puzzling. The **B version** captures what is right: that Albert has a belief about a particular individual (that we are now identifying as the evening star, even though Albert wouldn't so identify it in this context), a belief that it rises in the morning.

This solution requires that we make sense of quantification into belief contexts (the **B version**), so that we have a real distinction. (See the discussion of *the de re/de dicto distinction*.) The solution is also limited, because it applies only to versions of the puzzle that involve definite descriptions.

Stanford Encyclopedia of Philosophy
Supplement to Propositional Attitude Reports

The De Re/De Dicto Distinction

There is an important distinction in belief attributions, and, according to some, in the beliefs we attribute. W. V. Quine's example (Quine 1956) brings this out nicely through the recognition of an ambiguity in

> [1] Ortcutt believes that someone is a spy.

This could mean just that

> [2] Ortcutt believes that there are spies

or that Ortcutt has more interesting information:

> [3] Someone is an *x* such that Ortcutt believes that *x* is a spy.

The distinction here can be seen as a distinction of scope for the existential quantifier. In [2], the existential quantifier is interpreted as having small scope, within the propositional clause of the belief attribution.

> [2*] Ortcutt believes: $\exists x$, x is a spy.

In [3], however, the existential quantifier has large scope, selecting an individual and then ascribing a belief that relates Ortcutt to that particular individual.

> [3*] $\exists x$, Ortcutt believes that x is a spy.

The ambiguity in [1] and the simple way of distinguishing the two interpretations in [2*] and [3*] suggest that we are on to something. Russell's theory of definite descriptions employs just such a distinction in answering Frege's puzzles about belief. (See Definite descriptions.)

We just identified the distinction between [2*] and [3*] as a distinction in the scope of the quantifier. But [3*] also introduces something that needs a further account. On the standard semantics for quantification, the interpretation of [3*] requires that we be able to say when an individual *x* satisfies the open sentence ‘ Ortcutt believes that *x* is a spy’. Looked at another way, we no longer have a complete statement of a proposition in the propositional clause position in the sentence, since ‘that *x* is a spy’ does not express a proposition with a definite truth-value. Considerations like these have motivated the identification of a

distinction between *de dicto* belief attributions like [2] and [2*] and *de re* belief attributions like [3] and [3*]. The purely *de dicto* attribution relates Ortcutt to a *dictum*, a complete propositional content. The *de re* attribution relates him to a *res*, an individual that his belief is about. To say that an individual satisfies ‘Ortcutt believes that *x* is a spy’ is to say that Ortcutt has a *de re* belief about that individual. (For more on *de re* belief, see Quine 1956, Burge 1977.)

Although it may be tempting to think of these as an ambiguity in the verb ‘believe’, the section Ambiguity theories explains why this is not possible.

Indexicals

Indexicals are linguistic expressions whose reference shifts from utterance to utterance. ‘I’, ‘here’, ‘now’, ‘he’, ‘she’, and ‘that’ are classic examples of indexicals. Two people who utter a sentence containing an indexical may say different things, even if the sentence itself has a single linguistic meaning. For instance, the sentence ‘I am female’ has a single linguistic meaning, but Fred and Wilma say different things when they utter it, as shown by the fact that Fred says something false, while Wilma says something true.

Philosophers have several reasons for being interested in indexicals. First, they wish to describe their meanings and fit them into a more general theory of meaning. Second, they wish to understand the logic of arguments containing indexicals, including, for instance, Descartes's *Cogito* and various skeptical arguments that contain ‘I’ and other indexicals. Third, they think that reflection on indexicals may give them some insight into such matters as the nature of belief, self-knowledge, and consciousness.

---

1. Some Examples, Some Terminology, and Some Distinctions

1.1 Examples of Indexicals and Some Terminology

The indexicals that philosophers have studied most are the pronouns ‘I’, ‘he’, ‘she’, ‘this’, and ‘that’; the adverbs ‘here’, ‘now’, ‘actually’, ‘presently’, ‘today’, ‘yesterday’, and ‘tomorrow’; and the adjectives ‘actual’ and ‘present’. This list comes (more or less) from David Kaplan (1989a), whose work on indexicals is perhaps the most influential in the field.

An indexical's referent is determined, in part, by *extra-linguistic context* (for instance, the time and location of the speaker and the speaker's intentions). An indexical's referent can also vary from context to context. Thus indexicals are commonly called *context-sensitive expressions*. (The *content* of an indexical can also vary from context to context. This claim will be explained in section 3.1.)

1.2 Indexical and Non-indexical Uses of Pronouns

Some of the expressions in Kaplan's list have *non*-indexical uses. ‘He’, ‘his’, ‘she’, ‘her’, and ‘that’ are sometimes used like *bound variables* in formal languages. For example, the occurrence of ‘he’ in (1) (on the relevant understanding) functions like a variable that is bound by the quantifier phrase ‘every man’. Similarly, ‘her’ in (2) (under the appropriate reading) is bound by ‘every girl’.

1. Every man believes that he is smart.
2. Every girl loves her father.

These same pronouns are also sometimes used *anaphorically*. That is, some of their utterances seem to depend for their reference on prior linguistic context. (See the entry on anaphora.) For example, ‘he’ appears to be used anaphorically in discourse (3).

3. Johnny hit a home run. He was very happy.

Finally, there are the uses of these pronouns in which we shall be interested, the *indexical* (or

demonstrative or *deictic*) uses, as in (4) and (5).

4. He likes sardines [pointing at Fred], but he does not [pointing at Barney].
5. His car [pointing at Alfred] is dirty, but his car [pointing at Alonzo] is clean.

Most philosophers and linguists think that these different uses are closely related, and are not merely uses of distinct homonymous words. See section 5.4 for more on this topic. But in most of what follows, we shall ignore the non-indexical uses of these pronouns, and concentrate solely on their indexical uses.

1.3 Pure Indexicals and True Demonstratives

Kaplan (1989a) distinguishes between two different sorts of indexical, *pure indexicals* and *true demonstratives*. The true demonstratives include ‘he’, ‘she’, ‘his’, ‘her’, and ‘that’, while the pure indexicals include ‘I’, ‘today’, ‘tomorrow’, ‘actual’, ‘present’, and (perhaps) ‘here’ and ‘now’. (More on ‘here’ and ‘now’ below.) The two types of indexical differ in how their references are determined. The reference of an utterance of a true demonstrative is determined (in part) by the speaker's accompanying actions or intentions. For example, the reference of an utterance of ‘that’ is determined (in part) by the speaker's accompanying pointing gestures, or by the speaker's intention to refer to a particular object. (See section 2 for more on the nature of reference-fixing for true demonstratives.) The reference of a pure indexical is *not* determined by the speaker's actions or intentions in this way. For instance, an utterance of ‘I’ refers to the speaker, whether or not she points at herself, and an utterance of ‘tomorrow’ refers to the day after the day of utterance, regardless of the speaker's intention to refer to some particular day. We can say (loosely speaking) that the reference of pure indexicals is *automatic*, whereas the reference of true demonstratives requires something extra from the speaker.

From here on, we shall use the term ‘demonstrative’ to mean *true demonstrative*, in the above sense. ‘Indexical’ shall be used here as a generic term, so that it encompasses both (true) demonstratives and pure indexicals.

Kaplan includes ‘here’ and ‘now’ in his list of pure indexicals, but this seems inaccurate. Every utterance of ‘now’ automatically refers to a time interval that includes the moment of utterance, but the *extent* of the time interval surrounding the moment of utterance differs radically from utterance to utterance. Consider, for example, a typical utterance of ‘I am ready to leave now’ and a typical utterance of ‘People now ride in cars rather than horse-drawn carriages’. The extent of the time interval seems to depend on the speaker's intentions.[1] Similar remarks go for ‘here’ and the spatial extent of the location surrounding the location of utterance.[2] Thus it seems that ‘here’ and ‘now’ are demonstratives rather than pure indexicals.

1.4 Which Expressions are Indexicals?

Our initial list of indexicals in English (basically, Kaplan's list) is incomplete. A complete list would include at least the plural expressions ‘we’, ‘those’, ‘they’, and ‘theirs’ (for discussion of plural

indexicals, see Nunberg 1993). There are still more indexicals in English, but how many more is controversial.

Some philosophers and linguists (Reichenbach 1947, Partee 1973, Salmon 1989) claim that words and morphemes that indicate tense are indexicals, because (very roughly) they refer to different time intervals from context to context. Some have argued (Kratzer 1977, Lewis 1979b) that modal expressions, such as ‘necessarily’ and ‘possibly’, are indexical, because they vary in the type of modality they express from context to context (for example, nomological possibility in one context, metaphysical possibility in another). The subjunctive conditional connective "if it were the case that ... then it would be the case that ..." seems to be context-sensitive, because the range of possibilities relevant for determining the truth of such sentences seems to shift from context to context (see Lewis 1973, pp. 66-68). Utterances of ‘come’, ‘go’, ‘left’, and ‘right’ seem to invoke different points of reference, or different perspectives, in different contexts (see Fillmore 1972, 1975 and Lewis 1979b).

Some philosophers have claimed that propositional attitude verbs, like ‘believe’ and ‘know’, are indexicals. Richard (1990) claims that the sentences ‘Lois believes that Superman can fly’ and ‘Lois believes that Clark Kent can fly’ have the same truth value in some contexts, but different truth values in other contexts, though Lois undergoes no relevant changes. He argues that this occurs because, in different contexts, the verb ‘believes’ invokes different translation relations between the sentence inside the ‘that’-clause of the belief sentence and the sentences that the believer accepts; therefore, ‘believes’ expresses different relations in different contexts. (See the entry on propositional attitude reports.) Cohen (1988), DeRose (1995), and Lewis (1996) claim that the sentence ‘George knows that he has a hand’ can be false in a context in which the speaker is considering skeptical arguments, but can be true in another, more ordinary, context in which no skeptical arguments are under consideration, even though no relevant change occurs in George. They explain this by claiming that ‘know’ is an indexical that expresses different relations in different contexts, depending upon the relevant alternatives being considered in the speaker's context, or the standards of justification in force in the speaker's context.

The adjective ‘rich’ seems to be context-sensitive, for the truth value of ‘Myles is rich’ seems to vary from context to context, depending on which property or comparison class is salient in the context (for example, the class of all Americans, the class of philosophers, the class of university presidents, or the class of CEO's of large organizations). There are at least two competing accounts of this apparent context-sensitivity. On one, ‘rich’ is a unary predicate whose extension (and content) varies from context to context. On a second account, ‘rich’ is a binary predicate (*x* is rich for a *y*). Sometimes the second argument is linguistically supplied and pronounced, as in ‘Myles is rich for a philosopher’. But sometimes the second argument is unpronounced, as in ‘Myles is rich’, and in those cases, context supplies a property or comparison class to serve as the second argument of the binary predicate. The apparent context-sensitivity of other comparatives, such as ‘tall’, ‘large’, ‘heavy’, ‘hot’, and ‘fast’, might also be explained in either of these two competing ways. Some theorists (Partee 1989, Condoravdi and Gawron 1996) have argued in favor of the second sort of account for certain expressions that have indexical uses, such as ‘local’. In an utterance of ‘A local bar is selling cheap beer’, the utterance of ‘local’ refers to a location near the speaker. But in an utterance of ‘Every football fan watched the Superbowl at a local bar’, the utterance of ‘local’ does not refer to a location near the speaker. Rather, the utterance says that each

football fan *x* watched the Superbowl at some bar that is local to *x*. This can be easily explained if ‘local’ has a second argument position (*y* is local to *x*) whose value is supplied by context in the first case, but which gets bound by the quantifier ‘every football fan’ in the second.

According to Stanley and Szabo (2000), *all* nouns have a hidden argument position that can be bound or contextually filled. They use this claim to explain how different utterances of a single sentence containing a quantifier phrase can (apparently) quantify over different domains. For example, the claim made by ‘Every student is present’ can vary from context to context: in some contexts, an utterance of it claims that every student *who is in school S* is present, while in other contexts, such an utterance claims that every student *who is in class C* is present. Stanley and Szabo's theory entails that *every noun* is an indexical (and, perhaps, that every adjective, verb, and adverb is also).

On some views, the extensions (and contents) of *vague* expressions shift from context to context. ‘Bald’ is a paradigm case of a vague expression. Lewis (1979b) and Soames (1999) hold that, if David has an appropriate number and distribution of hairs on his head, then ‘David is bald’ may be true in one context and false in another. Lewis and Soames explain this by holding that the extension of ‘bald’ varies from context to context; Soames holds that it expresses different properties in different contexts. Both of them extend this same view to all vague expressions. Since nearly every expression is vague, their views imply that nearly every expression is an indexical.

Summarizing: indexicality in English extends beyond Kaplan's list, though how far beyond is controversial. In what follows, however, we shall concentrate on uncontroversial cases, and mainly on the expressions in Kaplan's list.

2. Reference-fixing for Demonstratives

One major topic of work on indexicals is reference-fixing for (true) demonstratives. As mentioned before, (true) demonstratives differ from pure indexicals, in that the reference of an utterance of a true demonstrative is not fixed "automatically" by the act of utterance alone. Something more is required to fix the reference of a demonstrative utterance. The nature of this "extra something" is controversial, but two obvious candidates are *pointing gestures* and *speaker's intentions*.

In his 1989a, Kaplan emphasizes the role of pointing gestures in fixing the reference of a demonstrative utterance. More precisely, he says that the reference of a demonstrative utterance is fixed by a *demonstration*. He describes a demonstration as "typically, though not invariably, a (visual) presentation of a local object discriminated by a pointing" (1989a, p. 490). Kaplan, however, changes his mind in his 1989b.[3] He there points out that a demonstration is "typically directed by the speaker's intention to point at a perceived individual on whom he has focused". He calls such intentions *directing intentions* and then says that he has come to "regard the directing intention, at least in the case of perceptual demonstratives, as criterial, and to regard the demonstration as a mere *externalization* of this inner intention." (1989b, p. 582)

Other theorists hold other views. Devitt (1981) says that the referent of an utterance of ‘that’ is the item that stands in a certain causal relation to the utterance. McGinn (1981) proposes that the referent of an utterance of ‘that *F*’ is the first *F* to intersect the line projected from the speaker's pointing finger. Wettstein (1984) says that the reference of ‘that’ is determined by the cues that a competent and attentive addressee would reasonably take the speaker to be exploiting. Reimer (1991a, 1991b) argues, contra Kaplan's later view, that demonstrative utterances can refer to objects that are not the targets of the speaker's directing intentions. Bach (1992a, 1992b) defends a version of Kaplan's later view from Reimer's criticisms; Bach says that the reference of a demonstrative utterance is fixed by certain of the speaker's communicative intentions.

One *prima facie* problem for demonstration-theories is that some utterances of demonstratives seem to refer even though the speaker does not produce a demonstration (for instance, a pointing gesture). If ‘here’ and ‘now’ are demonstratives (as suggested earlier), then they may present a particular difficulty for demonstration-theories, for demonstrations seem irrelevant to determining the referents of their utterances.

One *prima facie* problem for intention-theories is that speakers typically have a large number of intentions when they use demonstratives, and these intentions may conflict (as Bach recognizes in his 1992a and 1992b; see also Perry 1997). For example, a speaker who utters ‘he’ may intend to speak about Joe, and about the man that she (the speaker) sees over there, and about the man about whom others are speaking, and about the man at whom she (the speaker) is pointing. The speaker may think that these are the same person when they are not. Different intention-theories can select different of these intentions as reference-fixing, and so make different predictions about who the referent is in certain cases. Not all intention theories have been completely clear about what they take the relevant reference-fixing intention to be.

3. Kaplan's Theory of Indexicals

Thus far, we have not tried to describe the meanings of indexicals in any systematic way. In this section, we present one theory that attempts to do so, namely Kaplan's theory. We begin with Kaplan's theory because (as mentioned before) it is perhaps the most influential in the field. We first present an example that motivates some of Kaplan's distinctions. We then present Kaplan's theory. In section 4, we consider a criticism of Kaplan's theory, and some alternatives to Kaplan's theory.

3.1 An Example and Some Intuitive Distinctions

Many philosophers hold that indexicals have (at least) two different sorts of meaning. To see why, consider examples (6) and (7).

6. Fred: "I am female."
7. Wilma: "I am female."

There is a clear sense in which Fred's utterance and Wilma's utterance share a meaning, for they utter the very same unambiguous sentence. Let's say that their utterances have the same *linguistic meaning*. Nevertheless, their utterances also seem to differ in meaning, in some sense, for Fred and Wilma say different things: Fred says that *he* is female, whereas Wilma says that *she* is female. Moreover, Fred says something that is false, while Wilma says something that is true. Traditionally, this difference in truth value would be taken to show that Fred and Wilma assert different *propositions*. In view of these considerations, let's say that Fred's and Wilma's utterances differ in *content*, where the content of an utterance of a full indicative sentence is a proposition.

So far, we have an intuitive distinction between two sorts of meaning for utterances of indexical sentences: linguistic meaning and content. The theories of meaning that we shall consider below, beginning with Kaplan's, attempt to describe these (apparent) meanings more systematically.

Some theorists, however, do not find the above intuitions and distinctions compelling. Lewis (1980), for instance, thinks that these intuitions are shaky, at best; he, in any case, questions their significance for semantic theory. Philosophers who eschew meanings altogether (such as those who favor Davidsonian theories of meaning) seek semantic theories that ascribe only extensions to indexical expressions (e.g., truth values to sentences, and referents to singular terms), with respect to contexts and (perhaps) other indices. These theorists would not take the extra step of hypothesizing the existence of propositions or other sorts of meanings. See, for example, Burge (1974), Weinstein (1974), Larson and Segal (1995), and Lepore and Ludwig (2000). Nevertheless, in most of what follows, we concentrate on theories of meaning for indexicals that try to respect the above distinctions and intuitions in the most straightforward way possible, by hypothesizing (at least) two sorts of meaning.

3.2 Basics of Kaplan's Theory

In Kaplan's theory, linguistic expressions have contents *in*, or *with respect to*, *contexts*. Each context has at least an agent, time, location, and possible world associated with it.[4] The content of ‘I’ with respect to a context C is the agent of C; the content of ‘here’ is the location of C; and the content of ‘now’ is the time of C. The content of a predicate, with respect to a context, is a property or relation. The content of a sentence, with respect to a context, is a structured proposition, that is, a proposition that can have individuals, properties, and relations as *constituents*. The content of a sentence S with respect to C is made up of the contents of the words in S with respect to C.[5]

To illustrate, consider the sentence ‘I am female’. Suppose that the agent of context C is Fred. Then the content of ‘I’ in C is Fred himself, while the content of ‘is female’ in C is the property being-female. The content of the whole sentence, in C, is a proposition whose constituents are just these two items. We can represent this proposition with the following ordered pair.

<Fred, being-female>

The content of ‘I’ with respect to a context C* in which Wilma is the agent is Wilma herself, and the

content of ‘I am female’ in C* is the proposition <Wilma, being-female>. Thus the word ‘I’ and the sentence ‘I am female’ have different contents in different contexts.

The content of a sentence, with respect to a context, has a truth value *at the world of the context*. Kaplan therefore says that the content is either true or false *in the context*. For instance, the content of ‘I am female’, with respect to the above context C (in which Fred is the agent) is the proposition <Fred, being-female>. This proposition is false at the world of C (call this world ‘W’). So, Kaplan says that this proposition is false in context C. But the content of ‘I am female’ with respect to context C* (in which Wilma is the agent) is true with respect to the world of context C*, which is (also) W; so this second proposition is true in context C*.

On Kaplan's theory, we can also speak about the truth values of *sentences*, as opposed to contents (or propositions). The truth value of a *sentence* (as opposed to a proposition) depends on *two* parameters, context *and* world, on this theory. For example, the *sentence* ‘I am female’ is false with respect to C and W, but is true with respect to C* and W. (Notice that the world is the same both times, but the context is different.) Thus the sentence's truth value is *doubly-relativized*. This sort of double-relativization is often called *double-indexing*. (See Vlach 1973 and Kamp 1973 for early examples of semantic theories for indexicals that use double-indexing.)

The content of a sentence, with respect to a context, can be also evaluated for truth at a world other than the world of the context. For example, the content of ‘I am a philosopher’, with respect to C, is the proposition that Fred is a philosopher. This proposition is false at W (let's suppose). But this proposition is true at some other world, say W*, in which Fred is a philosopher. Thus, the *sentence* ‘I am a philosopher’ is false in C and W, but true at C and W*. (Notice that the context is the same both times, while the world is different.) Therefore, the sentence ‘It is *possible* that I am a philosopher’ is true with respect to C and W; and the content of the sentence, with respect to C, is true in C.

Kaplan identifies the linguistic meaning of an expression with its *character*, which is a function from contexts to contents that delivers the expression's content at each context.[6] So, for example, the character of ‘I’ is a function on contexts whose value at any context is the agent of the context; its value at a context in which Fred is the agent is just Fred himself, whereas its value at a context in which Wilma is the agent is Wilma. The character of ‘here’ is a function whose value at each context C is the location of C. The character of a simple predicate, like ‘is female’, is a function on contexts that delivers the appropriate property or relation at every context (in this case, the character delivers the same property at every context, namely being-female). The character of a sentence is a function from contexts to the structured propositional content of that sentence at each context.

Kaplan's theory can be extended to other indexicals, including demonstratives, by adding further suitable features to contexts. For instance, if each context has an associated day, then we can say that the content of ‘today’ in a context is the day of the context, and that its character is a function on contexts whose value at each context is the day of the context. The content of ‘you’ with respect to a context is the addressee of the context. The content of ‘that’ in a context is the demonstat*um* of the context. If we wish to deal with sentences that contain more than one occurrence of ‘you’ or ‘that’, then we can add

sequences of addressees and demonstrat*a* to contexts, and add subscripts to occurrences of ‘you’ and ‘that’; for instance, the content of ‘you_1’ is the first addressee of the context, the content of ‘you_2’ is the second, and so on. (See section 5.2 for more on multiple occurrences of demonstratives.)

We began in section 3.1 with some intuitions about Fred's and Wilma's *utterances* in (6) and (7). It's important to note that utterances are not the same as linguistic expressions; this is shown by the fact that in (6) and (7), Fred and Wilma produce *two* utterances of *one* linguistic expression (the sentence ‘I am female’). Rather, utterances are actions in which an agent utters an expression. Kaplan's theory does not, strictly speaking, ascribe contents or characters to utterances. It instead ascribes characters to *expressions* and contents to *expressions-in-contexts*, which we can think of as pairs of expressions and contexts. So, strictly speaking, Kaplan's theory does not directly confirm or disconfirm our initial intuitions about the meanings of Fred's and Wilma's utterances.

We can, however, *extend* Kaplan's theory to utterances in a rather natural way. (In fact, Kaplan often seems to have the following kind of extension of his theory in mind when he uses judgments about utterances to motivate his view.) Kaplan's theory ascribes a character to the *sentence* that Fred and Wilma utter. So a natural extension of Kaplan's theory would ascribe that character to their two utterances of the sentence. Fred's utterance has a certain agent (Fred himself), and occurs at a certain time, place, and world. Kaplan's theory ascribes a content to the sentence ‘I am female’ with respect to a context with Fred as its agent, and with that associated time, place, and world. So a natural extension of Kaplan's theory could assign this content to Fred's utterance. Similarly, with appropriate changes, for Wilma's utterance. This extension of Kaplan's theory does confirm our intuitions about (6) and (7). (But this extension of Kaplan's theory also has some limitations; see sections 5.2 and 5.3 below.)

3.3 Logic, Logical Truth, Validity, and Necessity

Kaplan's (1989a) formal theory contains an elaborate logic. We shall concentrate here on aspects of the logic that can be understood without going into formal details.

Recall that a sentence S is true in a context C iff the content of S in C is true in the world of C. So, for instance, if the agent of context C is Fred and the world of C is W, then ‘I am hungry’ is true in C if and only if the proposition that Fred is hungry is true in world W. Consider now the sentence ‘If I am hungry, then I am hungry’. This sentence is true in every context. Kaplan says that a *logical truth* is a sentence that is true in every context.[7] Thus Kaplan's theory validates our intuition that this sentence is a logical truth. Kaplan says that an argument is *valid* iff: for every context C, if the premises of the argument are true in C, then the conclusion is true in C. Under this definition of validity, arguments (8) and (9) are valid.

8. I think. Everything that thinks exists. Therefore, I exist.
9. This is a hand. If this is a hand, then I am not a brain in a vat. Therefore, I am not a brain in a vat.

Thus Kaplan's logic for indexicals might help us understand the logic of some philosophically interesting

arguments. (For further discussion of the logic of indexicals and its relevance to Descartes's *Cogito*, see Forbes forthcoming.)

There are logical truths that are peculiar to indexical expressions in Kaplan's system. For instance, Kaplan supposes that, for any context, the agent of the context exists in the world of the context. Thus the sentence ‘I exist’ is true in every context, and counts as a logical truth. (Therefore, argument (8) is valid simply because its conclusion is valid. This may be relevant to the interpretation of Descartes's *Cogito*. See Forbes forthcoming.) Kaplan further supposes that for every context C, the agent of C is located at the time and place of C. Thus the sentence ‘I am here now’ is true in every context, and is a logical truth. (For critical discussion, see Vision 1985 and Salmon 1991.)

However, in most contexts, the contents of these sentences will be *contingent*, that is, true but not necessary. Consider the sentence ‘I exist’. It is a logical truth, according to Kaplan's theory. But its content with respect to a context in which Fred is the agent is the proposition that Fred exists. Since Fred could have failed to exist, this proposition is contingent. Thus, on Kaplan's theory, ‘I exist’ is a logical truth whose content, in many contexts, is contingent. (Similarly for ‘I am here now’.) Now if ‘I exist’ is a logical truth, then it's reasonable to think that Fred knows *a priori* the proposition that he expresses when he utters ‘I exist’ (at least when Fred considers the proposition in that way). If he does know this proposition *a priori*, then Fred has *a priori* knowledge of a contingent proposition. Kaplan thus claims that his logic of indexicals provides examples of Kripke's (1980) contingent *a priori*. (For discussion, see Salmon 1991 and Forbes 1989, forthcoming.)

3.4 Direct Reference and Rigid Designation

Kaplan (1989a) claims that indexicals are devices of *direct reference*. By this he means that the *content* of an indexical, with respect to a context C, is simply the object to which it refers in C; its content is *not* a property (or descriptive condition) that determines the referent. For instance, the content of ‘I’ in C is just the agent of C; its content in C does *not* include the property of being-the-agent-of-C, or any other sort of property.[8]

Kaplan (1989a) also says that indexicals are *rigid designators*. The notion of a rigid designator comes from Kripke (1980), who defines a rigid designator to be an expression that has the same extension (or referent) with respect to all possible worlds.[9] When Kaplan claims that indexicals are rigid designators, he means (roughly) that, once a referent for an indexical is determined by a context, that same object is the one that is relevant for determining the truth value of a sentence containing that indexical at all worlds. For example, if Fred is the agent of context C, then *Fred's* state of hunger (and no one else's) is what is relevant for determining the truth of ‘I am hungry’ with respect to C and any world W whatsoever (whether or not W is the world of C, and whether or not Fred utters ‘I’ in W).

To state Kaplan's view more precisely, let's recall that we earlier spoke of both the *content* of a sentence with respect to a context, and the *truth value* of a sentence with respect to a context *and* a world (the truth value of the *sentence* was doubly-relativized). We can similarly speak of the *content* of a *singular term*

with respect to a context, and its *referent* with respect to a context *and* a world.[10] The definite description ‘the person who invented bifocals’ has the same *content* with respect to all contexts; this content includes the property of being-a-person, the relation of inventing, and so on. But the *referent* of ‘the person who invented bifocals’, with respect to a context *and* a world, varies from world to world, because the person who invented the bifocals varies from world to world. The situation is reversed for ‘I’, Kaplan claims. The content of ‘I’ varies from context to context: its content is Fred in one context, Wilma in another, and so on. But given a single context C, the referent of ‘I’ with respect to C and world W is the same for any world W whatsoever. For instance, if Fred is the content of ‘I’ with respect to context C, then the referent of ‘I’, with respect to C and any world W whatsoever, is Fred. Thus, for all worlds W, ‘I am hungry’ is true at C and W if and only if *Fred* is hungry in W. Therefore, Kaplan says that ‘I’ is a rigid designator.[11]

Kaplan says that all directly referential expressions are rigid designators: if the content of an expression (at a context) is an individual, then that individual is the referent of that expression at that context and any world whatsoever. However, some rigid designators are not directly referential. For instance, the referent of the expression ‘the sum of 2 and 3’ with respect to any context and any world is the number 5, and so this expression is a rigid designator. But the expression ‘the sum of 2 and 3’ is not directly referential, for its content (in a context) is not simply an individual (like the number 5), but is instead a complex object whose constituents include the numbers 2 and 3, and the relation *x*-is-a-sum-of-*y*-and-*z*.

4. A Criticism of Kaplan's Theory and Some Alternatives

4.1 Some Preliminaries Concerning Belief and Cognitive Significance

Kaplan's theory is by no means universally accepted. The most common objections to Kaplan's theory concern *belief* and *cognitive significance*.[12] To understand the apparent problems, consider Fred's utterance in (10).

10. Fred: "You are hungry" [addressing Barney].

Let's suppose that Fred *assertively* utters the sentence. Then it seems that he *asserts* the *proposition* that his utterance expresses. If this proposition is the same as its (alleged) Kaplanian content, then he asserts the Kaplanian content.[13] Furthermore, if Fred utters the sentence *sincerely*, then he *believes* the proposition that his utterance expresses. Now according to Kaplan's theory, the content of Fred's utterance is a singular proposition, that is, a proposition that contains an individual as a constituent, in this case Barney. Many philosophers think that singular propositions could not be the things that people believe, and so Kaplan's theory cannot account for the cognitive significance of indexicals. What follows is an example intended to show this.

4.2 An Example and a Criticism of Kaplan's Theory

Imagine that Fred is looking at Barney, but that Barney is turned so that Fred directly sees only his left side. Suppose that, at the same time, Fred is viewing Barney's right side indirectly, via a mirror. Suppose the right side of Barney's face is masked; suppose finally that Barney is wearing a very unusual costume, in which the left side appears to be a business suit while the right side appears to be a pair of swimming trunks. Then Fred might reasonably and sincerely utter (11), while addressing Barney and pointing at the mirror image.

11. You [addressing Barney] are wearing a business suit, but he [pointing at the mirror] is not wearing a business suit.

On Kaplan's view, the content of Fred's utterance of (11) is a proposition that contains Barney as a constituent twice over. It is the proposition that Barney is wearing a business suit, but Barney is not wearing a business suit. Thus, on Kaplan's theory, Fred believes a contradictory proposition, one whose immediate constituents are a proposition and its negation. But Fred (let us suppose) is a perfectly rational person. So he would never believe an outright contradiction. Therefore, many philosophers conclude, Kaplan's theory of indexicals is incorrect.

4.3 Some Alternatives to Kaplan's Theory

The objection is a variant on Gottlob Frege's puzzle of cognitive significance (see also the entries on the sense/reference distinction, and propositional attitude reports). Frege (1892) uses puzzles like this to motivate his semantic theory, and so we might first look to him to find a solution to the problem. Frege (1984) contains a brief discussion of indexicals. One view that can be extracted from this article, together with Frege (1892), is the following. Utterances of expressions have both a referent and a *sense*. The sense of an utterance of a full sentence is a *thought*. A person who sincerely and assertively utters a sentence asserts and believes the thought (sense) expressed by that utterance. (Thus, sense plays roughly the same role in this Fregean theory that content does in Kaplan's.) The sense of an utterance of an indexical, like ‘you’, can also be expressed by an utterance of a definite description *that contains no indexicals*. The relevant definite description is one whose utterance would be cognitively equivalent, for the speaker, to the utterance of the indexical. The referent of the utterance of the indexical is the referent of the relevant definite description.

It is controversial whether Frege really held this theory about indexicals, especially the thesis that utterances of indexicals have senses that can be expressed by non-indexical definite descriptions. Nonetheless, let us call it *Frege's theory*

On Frege's theory, the sense of Fred's utterance of ‘you’ might also be expressed (roughly) by the definite description ‘the person wearing a business suit’. The sense of Fred's utterance of ‘he’ might be expressed (roughly) by ‘the person wearing swimming trunks’. Thus the thought expressed by Fred's utterance of the full sentence in (11) might also be expressed by ‘the person wearing a business suit is wearing a

business suit, but the person wearing swimming trunks is not'. The thought expressed by the latter sentence is not contradictory. Therefore, Fred does not believe a contradiction, according to Frege's theory. Thus Frege's theory seems to solve the apparent problem with Kaplan's theory.

But Perry (1977) and Kaplan (1989a) have argued that there are problems with Frege's own theory. (For related discussion, see also Burks 1949 and Castaneda 1966, 1967.) Suppose that Fred sincerely utters 'Today is July 4, 2001' on July 3, 2001. According to Frege's theory, there is some non-indexical description that captures the sense of Fred's utterance of 'today'. But, as Perry (1977) points out, Fred may find it very difficult to produce a non-indexical description that he would be willing to substitute for his utterance of 'today' and that uniquely picks out one day. (In fact, in the previous paragraph the definite descriptions that we substituted for Fred's utterances of 'you' and 'he' almost certainly do not have unique referents.) Moreover, Perry says, it's possible that any such description that Fred would provide would not refer to the same day as his utterance of 'today'. For instance, Fred might be inclined to express the sense of his utterance of 'today' with the description 'the day in 2001 during which Americans celebrate the signing of the Declaration of Independence'. If so, then Frege's theory entails that Fred's utterance of 'today' on July 3, 2001 refers to July 4, 2001. So Frege's theory entails that Fred's utterance of 'Today is July 4, 2001' is true, and that he asserts and believes a truth. But Fred's utterance is false (no matter how he is inclined to describe the day on which he produces his utterance), and he asserts and believes a falsehood. So Frege's theory is incorrect. Kaplan raises a related *modal* problem for Frege's view. Suppose that Fred utters 'If I exist, then I am speaking', and suppose that the sense of his utterance of 'I' can be expressed by 'the person speaking'. Then on Frege's theory, Fred's utterance expresses the same sense as 'If the person speaking exists, then the person speaking is speaking'. This expresses a necessary truth, but Fred's utterance clearly does not.

One further apparent difficulty with Frege's view is that two utterances containing indexicals would rarely, if ever, express the same sense (or have the same content, to use our previous terminology). Consider, for example, (12) and (13).

12. Fred: "I am hungry."
13. Wilma: "You are hungry" [addressing Fred].

We are inclined to say that Fred's and Wilma's utterances say the same thing (in some sense). Furthermore, we think that Fred and Wilma (in some sense) assert and believe the same thing. Kaplan's theory validates these judgments, for their utterances have the same Kaplanian content, namely the singular proposition that Fred is hungry, and Fred and Wilma assert and believe that proposition. But it's highly unlikely that Fred's utterance and Wilma's utterance would express the same descriptive Fregean sense.

Schiffer (1978, 1981) avoids some of the problems with Frege's theory by allowing the relevant definite descriptions to contain the indexicals 'I' and 'now'. For instance, on Schiffer's theory, Fred's utterance of 'you' in (11) might be cognitively equivalent, for him, to the description 'the person whom I am now addressing', while his utterance of 'he' might be cognitively equivalent to 'the person whom I am now viewing in a mirror'. If so, then, on Schiffer's theory, Fred believes a singular proposition, but one that is

not contradictory. Such a theory may avoid Perry's "wrong referent" objection, for the "I-now" description that Fred would use to replace ‘today’ would probably be something like ‘the day during which I am now speaking’, which would pick out the correct day. Kaplan's objection concerning ‘I’ and modality would be avoided, because an utterance of ‘I’ would have the speaker as its content. Schiffer avoids the problem of two utterances' never having the same content by distinguishing between the semantic content of an utterance and the proposition that the speaker believes. On Schiffer's view, Fred's utterance and Wilma's utterance have the same semantic content, namely the singular proposition that Fred is hungry. But Schiffer denies that Fred and Wilma believe the same singular proposition.

Schiffer, however, does not avoid all of the apparent problems raised above. On his view, two people will only very rarely believe the same proposition containing a contingent individual as a constituent. Moreover, Schiffer denies that we typically believe what we say; that is, we often do not believe the propositions that are the semantic contents of our utterances. Finally, Schiffer's view entails that certain utterances that seemingly express the speaker's contingently true beliefs actually express necessarily true beliefs. For instance, if the belief content that Fred expresses by uttering ‘you’ in (11) can be expressed by ‘the person whom I am now addressing’, then an utterance by Fred of ‘If you exist, then you are the person whom I am now addressing’ would express his belief in a necessarily true proposition; but it seems that he is expressing his belief in a contingent proposition. Austin (1990) presents further criticisms of this view.

Lewis (1979a) and Chisholm (1981) use examples like (11) to argue that people believe *properties* rather than propositions. These properties are roughly expressible by phrases or sentences containing ‘I’ and ‘now’. For example, according to Lewis and Chisholm, Fred in example (11) believes a property which might be expressed as follows: being a thing that addresses exactly one person, who is wearing business suit, and that views through a mirror exactly one person, who is not wearing a business suit. We might use ‘I’ and ‘now’ to express this property as follows: I am now addressing exactly one person, who is wearing a business suit, and viewing exactly one person through a mirror, who is not wearing a business suit. In many respects, Lewis's and Chisholm's theories of indexical belief are very similar to Schiffer's theory. (Their theories of *meaning* might not be alike: Chisholm, unlike Schiffer, holds that such properties are not only the objects of belief, but also the contents of utterances.) Thus Chisholm's and Lewis's theories are subject to some of the same difficulties as Schiffer's, as Austin (1990) points out.[14]

Evans (1981) proposes that the content of an utterance of an indexical consists (roughly) of the speaker, or the time of utterance, together with a relation that resembles its Kaplanian character. On this view, Fred's utterance of ‘you’ in (11) is (roughly representable by) an ordered pair whose first member is Fred and whose second member is (roughly) the relation *addressing*. Together, the members of this pair gives us a property, being-a-thing-that-Fred-addresses, that picks out Barney. The content of Fred's utterance of ‘he’ in (11) consists of Fred plus (roughly) the relation *demonstrating*. This pair also determines a property that picks out Barney. Nevertheless, on Evans's view, Fred's utterance does not express a contradictory proposition. In some important respects, Evans's proposal resembles that of Schiffer, Lewis, and Chisholm, and may be subject to some of the same difficulties. For instance, on Evans's view there is no sense in which Fred and Wilma say or believe the same thing in examples (12) and (13). Evans's theory might also be vulnerable to modal objections similar to those that seemingly afflict these other theories, if

the theory is filled out in certain natural ways.

Peacocke (1992) proposes a neo-Fregean theory according to which senses, or *concepts (*as he calls them), are primitive, irreducible entities. However, each concept can be uniquely identified by describing the conditions under which a thinker grasps that concept (that is, by describing conditions under which a person can entertain a proposition that contains that concept as a constituent). The indexical concepts fall into types, e.g., first-person concepts and perceptual demonstrative concepts. For instance, in example (11), Fred grasps both a 'you' concept and a 'he' concept. (If Fred were in a perceptually identical situation, but looking at Barney's twin rather than Barney, then Fred would be grasping different 'you' and 'he' concepts, though they would be similar in type.) We can uniquely describe the concept Fred grasps by saying what it takes for a person to grasp that concept (we will not attempt to describe those conditions here). Peacocke's theory avoids many of the objections to Frege's theory. However, Peacocke's theory entails that Fred and Wilma believe different propositions in example (12)-(13). It's not entirely clear whether Peacocke's theory is vulnerable to modal objections.

4.4 Kaplanian Responses to the Criticism

The above survey of alternatives to Kaplan's theory was initially motivated by an apparent problem that Kaplan's theory has with cognitive significance and belief. Let's now consider how adherents to Kaplan's theory have responded to this problem. Consider once again the example of Fred in (11).

11. You[addressing Barney] are wearing a business suit, but he [pointing at the mirror] is not.

The difficulty was that, on Kaplan's theory, Fred seems to assert and believe a contradictory singular proposition, one that contains the singular proposition that Barney is wearing a business suit, and the negation of that very same proposition.

In reply, Kaplan (1989a) and Perry (1979) hold that a singular proposition can be entertained and believed *in different ways*. These ways of entertaining and believing a proposition correspond to characters. Thus Kaplan says that an agent can believe a proposition *under* one character, but fail to believe it under another character. For instance, Fred in (11) believes the proposition that Barney is wearing a business suit *under* the character of 'You are wearing a business suit', but fails to believe that proposition *under* the character of 'He is wearing a business suit'; in fact, Fred believes the negation of that proposition under the character of 'He is *not* wearing a business suit'. On Kaplan's view, Fred really does believe a contradictory proposition, but he believes the conjuncts of this proposition under suitably different characters, which is why he still counts as rational.

Perry (1979) elaborates on this view by distinguishing between (i) the proposition that an agent believes and (ii) the *belief state* in virtue of which the agent believes that proposition. For any one proposition, there are many belief states that would enable an agent to believe that proposition. An agent can be in one of these belief states, while failing to be in another. Belief states can be classified into types according to the characters of the sentences that they dispose the agent to assert. For instance, a belief state that would

cause an agent to sincerely assert ‘You are wearing a business suit’ is distinct from a belief state that would cause him to sincerely assert ‘He is wearing a business suit’, because the two sentences differ in character. A rational agent could be in a belief state of the first type without being in a belief state of the second type. In fact, a rational agent could be in the first sort of belief state, while also being in a second sort that causes him to utter ‘He is *not* wearing a business suit’. Thus a rational agent could believe a proposition and its negation, as long as he does so by being in suitably different belief states.

Kaplan's response leaves us with the question "What does it mean to believe a content *under* a character?" Perry's postulation of belief states is a first step towards answering the question, but his work leaves the nature of belief states relatively unclear. Both Kaplan and Perry think that ways of believing either are, or correspond one-to-one with, characters. This assumption is problematic. We can easily imagine that Fred, while viewing Barney, says ‘He [pointing directly at Barney] is wearing a business suit, but he [pointing at the mirror] is not’. If the two occurrences of ‘he’ have the same character, then, on Kaplan's and Perry's view, Fred rationally believes a proposition under one character and the negation of that same proposition under the "negation" of that same character. This is exactly the sort of situation that Kaplan's and Perry's view should disallow. For further discussion and criticisms, see Wettstein (1986), Taschek (1987), and Crimmins (1992, chapter 1). For elaborations on, and modifications of, the Kaplan-Perry theory, see Perry (1997). See also section 5.2 for related issues.

5. Other Topics Concerning Indexicals

In this section, we discuss a variety of additional issues about indexicals.

5.1 Complex Demonstratives

Complex demonstratives are expressions of the form *that N* or *this N*, where *N* is a common noun phrase. Examples include ‘this dog’, ‘that red car’, and ‘that woman who is standing by the door’. Complex demonstratives raise at least two interesting questions. First, do the common noun phrases that appear in them play some role in determining their referents? For example, must a person be a crook in order to be the referent of an utterance of ‘that crook’? Second, what do these common noun phrases contribute to the contents of complex demonstratives? For instance, does an utterance of ‘That crook is untrustworthy’ express a proposition that has the property of being-a-crook as a constituent? Or does the phrase ‘that crook’ contribute only its referent to the proposition expressed?

Many (though not all) theories of complex demonstratives can be classed into three types, according to how strong a semantic role they attribute to the common noun phrases. The first type says that the common noun phrase in a complex demonstrative plays *no* semantic role in determining the referent of the complex demonstrative; so a person could be the referent of an utterance of ‘that crook’ even if she is not a crook. Furthermore, this type of view says that the content of the common noun phrase is *not* a constituent of the content of the complex demonstrative; the content of an utterance of a complex demonstrative is just its referent. The common noun phrase serves merely as a pragmatic cue that helps the speaker's audience figure out what the speaker's intended referent is. Call theories of this sort *minimal*

theories, because they assign a minimal, or non-existent, semantic role to the common noun phrase. Larson and Segal (1995) endorse (roughly) a minimal theory (they do not, however, accept the existence of Kaplan-style contents).

Theories of the second type say that the common noun phrase *does* help determine the referent, but say that its content does *not* appear as a constituent of the content of the complex demonstrative. On such views, a person must be a crook in order to be the referent of an utterance of ‘that crook’, but the property of being-a-crook is not a constituent of the complex demonstrative's content. The content of the complex demonstrative is just its referent. Kaplan (1989a) does not explicitly endorse this type of theory, but his incidental remarks about complex demonstratives suggest that he would favor it. Braun (1994) and Borg (2000) argue explicitly for this sort of view. Call theories of this sort *intermediate theories*.

Theories of the third type say that the common noun phrase helps determine the referent; moreover, the content of the common noun phrase appears as a constituent of the content of the complex demonstrative. Richard (1993) and King (2000) endorse views of this sort. (King holds, in addition, that complex demonstratives are quantifier phrases that are comparable, in many respects, to definite descriptions.) Let's call theories of this sort *maximal theories*.

Advocates of minimal theories describe cases in which a speaker apparently refers to a person with an utterance of ‘that crook’, even though the person is not a crook. But advocates of intermediate and maximal theories reply by distinguishing between *speaker referent* and *semantic referent* (see Kripke 1977): they say that, in such cases, the *speaker* refers to the non-crookish person, but the speaker's *utterance* does not semantically refer to that person. Some advocates of maximal theories claim that sentences like (14) are logically or analytically true, whereas (they claim) this would not be so on minimal and intermediate theories, because those theories say that the content of the common noun phrase is not part of the content of the proposition expressed.

14. If that crook exists, then that crook is a crook.

Advocates of intermediate views respond by admitting that (14) is true in all contexts (ignoring reference failure). But (they claim) this is not because the content of ‘crook’ is part of the content of the complex demonstrative. Rather, (14) is true in all contexts because ‘that crook’ refers in a context to a person only if the relevant person is a crook in the world of that context. Therefore, if the antecedent of (14) is true in a context, then so is its consequent. Intermediate theorists point out that (15) seems to be false in many contexts, which seems contrary to maximal theories.

15. Necessarily: if that crook exists, then that crook is a crook.

Maximal theorists, however, sometimes add rigidifying devices to the contents of complex demonstratives to avoid this difficulty. They furthermore point to cases of apparent quantification into complex demonstratives, which seem to present a difficulty for intermediate theories.

Obviously, the issues and arguments here are quite complicated. Moreover, intuitions about the relevant cases are often unstable. For further discussion, see the works mentioned above. See also Dever (2001) and Lepore and Ludwig (2000), whose views do not fit easily into the above classification scheme.

5.2 Multiple Occurrences of Demonstratives

Kaplan's theory has an apparent problem with sentences that contain multiple occurrences of the same demonstrative. The problem can be presented as an argument from Kaplanian premises to apparently false conclusions, as follows. The demonstrative ‘that’ has a single linguistic meaning. So every occurrence of ‘that’ has the same linguistic meaning. If Kaplan's theory is correct, then the linguistic meaning of an expression is its character. Thus, if Kaplan's theory is correct, then every occurrence of ‘that’ has the same character. Thus both occurrences of ‘that’ in sentence (16) have the same character.

16. That is not identical with that.

But if the two occurrences of ‘that’ in (16) have the same character, then they have the same referent and content in every context. Thus, (16) is false in every context.[15] But this is surely incorrect. If we extend Kaplan's theory to utterances in the natural way suggested in section 3.2, we get the clearly absurd result that no utterance of (16) is true.

Kaplan seems to try to escape this consequence by, in effect, making the word ‘that’ ambiguous. On one version of his theory, the single word ‘that’ is replaced with the subscripted expressions ‘that_1’, ‘that_2’, etc. The content of ‘that_1’ in a context is the first demonstratum of the context, the content of ‘that_2’ is the second demonstratum, and so on. Thus (17) is true in contexts in which the first demonstratum is distinct from the second.

17. That_1 is not identical with that_2.

However, each subscripted ‘that’ has a different character (which is perhaps why Kaplan [1989b] sometimes speaks of the "exotic ambiguity" of demonstratives). None of these characters is a reasonable candidate for being *the* linguistic meaning of the (unsubscripted) English word ‘that’. So the subscript-maneuver undercuts Kaplan's identification of linguistic meaning with character.[16]

There are several ways in which one might try to deal with this problem. One is to allow shifts in context in mid-sentence. We could allow the content of ‘that’ in a context to be *the* demonstratum of the context. We could then suppose that the two occurrences of ‘that’ in (16) are (always or sometimes) evaluated for content in *different* contexts that may have different demonstrata. Unfortunately, this option may wreak havoc with the logic of demonstratives; it may, for instance, undermine attempts to allow argument (9) (in section 3.3) to be valid. A second option is to give up the identification of linguistic meaning with character, and suppose instead that linguistic meaning is a third sort of meaning, distinct from both character and content. A third option is to move away from a Kaplan-style theory, which assigns contents

to expressions-in-contexts, and move to a theory that assigns contents to utterances. This might help because every *utterance* of (16) contains *two utterances* of ‘that’. There are almost certainly other options. For further discussion, see Kaplan (1989b, 1999), Wettstein (1986), Braun (1996), Garcia-Carpintero (1998), Richard (1992, forthcoming), Forbes (forthcoming), and section 5.3 below.

5.3 Utterance Theories vs. Expression Theories

As mentioned earlier, an *utterance* is an action (a sort of event) in which an agent utters an expression. Kaplan's theory does not, strictly speaking, assign contents to utterances. Rather, it assigns contents to *expressions-in-contexts*, which we can think of as pairs of expressions and contexts. There are many expressions-in-contexts for which there is no corresponding utterance. For instance, consider a context in which Fred utters ‘I am wearing a business suit’, and nothing else, at a particular time, place, and world. Even though Fred does *not* utter ‘I am hungry’ at that time, place, and world, there is still an expression-in-a-context consisting of that sentence together with a context which has Fred as its agent, and which has that time, location, and world associated with it. Kaplan's theory assigns a content to this expression-in-a-context (namely, the proposition that Fred is hungry) even though Fred does not utter the expression at that time, place, and world. That content even has a truth value in that context. Thus Kaplan's theory of indexicals "abstracts away" from utterances to a remarkable degree.

Kaplan (1989a, 1989b) claims that his abstract, *expression-based*, theory of indexicals has various advantages, especially when it comes to logic. First, Kaplan claims that his expression-theory classifies as logical truths all sentences that should be logical truths, whereas utterance-theories do not. Consider, for example, sentences of the form *If P then P*. All such sentences are logical truths, Kaplan claims, and are so-classified on Kaplan's theory. But now consider a sentence of this form in which P is an extremely long sentence containing ‘today’. Then there may be utterances of this sentence in which the utterance of the antecedent is true, while the utterance of the consequent is false, simply because the first utterance of P has taken more than one day to complete. If a sentence is logically true iff all of its *utterances* are true, then this sentence is *not* a logical truth, even though it has the form *If P then P*. But this seems incorrect. Second, Kaplan claims that his approach correctly labels some sentences as *not* logically true which would be incorrectly labeled as logically true on utterance-based theories. For instance, on Kaplan's abstract approach, the sentence ‘I am uttering something’ is *not* a logical truth, because it is false with respect to contexts in which the agent of the context is silent. But all *utterances* of this sentence are true, so if logical truth were taken to be truth-of-all-utterances, then this sentence would be (incorrectly) classified as a logical truth.

However, there also seem to be disadvantages to Kaplan's expression-based theory. As Kaplan (1989b) notes, there are serious difficulties in assigning contents to *true demonstratives* with respect to contexts in which the agent does not have any relevant directing intentions and produces no demonstrations. Suppose, for example, that when Fred utters ‘I am wearing a business suit’ at time T, location L, and world W, he does *not* point at any object and does *not* intend to refer demonstratively to any object. Then it will be very difficult to assign a content to ‘That is a dog’ with respect to a context that has Fred as its agent, and which has T, L, and W as its associated time, place, and world. Moreover, Kaplan's apparent problem with multiple occurrences of demonstratives is at least partly due to his assigning contents to expressions-

in-contexts.

Other theorists prefer more utterance-oriented approaches to indexicals: see, for instance, Reichenbach (1947), Burks (1949), Weinstein (1974), and Barwise and Perry (1983). Perry (1997) argues for the advantages of theories that focus primarily on utterances. Kaplan himself (Kaplan 1999) has recently taken a more positive view of utterance-based theories. For further discussion, see Braun (1996), Garcia-Carpintero (1998) and Forbes (forthcoming).

5.4 Variables, Anaphora, and Demonstratives

As mentioned in section 1.2, many of the expressions that can be used as demonstratives, such as ‘he’ and ‘she’, can also be used anaphorically and in ways similar to bound variables in formal languages. This presents a difficult challenge to semanticists. On the one hand, there are significant semantic differences between variables, anaphora, and demonstratives: for instance, the content of a demonstrative is determined by a speaker's intentions or demonstrations, while the content of a (free) variable is determined arbitrarily by an assignment of values to variables. But, on the other hand, it seems that ‘she’ is an *un*ambiguous expression, which has a single linguistic meaning. The challenge for semanticists is to describe the linguistic meaning of ‘she’ without slighting the significant semantic differences between its various use. (Similarly for ‘he’, ‘his’, ‘her’, and so on.)

Many theorists have discussed aspects of this problem, but it is unclear whether any have fully met the challenge. Kaplan (1989a, 1989b) emphasizes the semantic similarities between (on the one hand) free variables under assignments and (on the other hand) demonstratives in contexts. But he backs away from identifying the linguistic meanings of ‘he’ and ‘she’ with the linguistic meanings of variables (with appropriately restricted ranges); he even entertains the possibility that there are two homonymous expressions ‘he’, one of which is a demonstrative and the other of which is a variable. Other theorists (for instance, Heim and Kratzer 1998, chapter 9) assimilate demonstratives to free variables. Those who work on discourse representation theory and dynamic semantics emphasize the similarities between variables and some anaphoric uses of pronouns. (See, for example, Kamp and Reyle 1993 on discourse representation theory, and Chierchia 1992 on dynamic semantics; see also the entry on anaphora.) For related discussion, see Partee (1989) and Condoravdi and Gawron (1996).

Stanford Encyclopedia of Philosophy
Notes to Indexicals

Notes

1. Smith 1989 says that some uses of ‘now’ do not refer to a time interval that includes the moment of utterance. For instance, when narrating the life of George Washington, one might say ‘Washington now needed to get across the Delaware River’.

2. Kaplan 1989a attributes to Michael Bennett the observation that some uses of ‘here’ are demonstrative, as when a person points at a map and says ‘Next week, I'll be *here*’.

3. Kaplan's manuscript "Demonstratives" (Kaplan 1989a) was written in the 1970's and circulated informally for many years before being published. Kaplan's "Afterthoughts" (Kaplan 1989b) was written considerably later, even though it has the same official publication date as "Demonstratives."

4. Strictly speaking, Kaplan (1989a) associates a *circumstance of evaluation* with each context, rather than just a possible world. A circumstance of evaluation is a pair of a possible world and a time. We shall ignore this refinement in the presentation that follows.

5. In his informal presentations of his theory, Kaplan (1989a, 1989b) identifies contents with individuals, properties, relations, and structured propositions, as we have done here. But when he turns to technical matters, these contents are identified with (or represented by) *intensions*, which are functions from circumstances of evaluation to extensions. For details, see Kaplan 1989a and Forbes 1989, forthcoming. We shall concentrate here on the less formal aspects of Kaplan's theory.

6. Sometimes Kaplan describes the character of an expression as being a *rule* for associating contents of the expression with contexts. In his more technical presentations, Kaplan (1989a) seems to identify the character of an expression with a function different from that described in the main text. See Braun 1995.

7. More accurately, a logical truth is a sentence that is true in every context *in every structure* (or model). From here on, we ignore this qualification.

8. Three points: (i) Kaplan tends to restrict application of the term ‘directly referential’ to singular terms. (ii) Kaplan (1989a) holds that the notion of direct reference can be defined without appeal to the notion of a singular proposition, but he does not explicitly provide any such definition. (iii) In the preceding paragraph, we used the notion of the referent of an expression with respect to a (Kaplanian) context. See the next two paragraphs, and note 10, for a discussion of this notion.

9. In fact, it is somewhat difficult to determine exactly how Kripke (1980) wishes to define ‘rigid designator’. For discussion, see Kaplan 1989a, 1989b and Salmon 1981.

10. When we speak of the referent of a term with respect to context C, we mean its referent with respect to C *and* the world of C.

11. We can say more precisely what it means for an indexical to be a rigid designator, but we must first modify Kripke's original definition of ‘rigid designator’ so that it can be extended to context-sensitive expressions. We first need to assume (or define) the notion of the *referent of a singular term with respect to a context C and world W*. Then the following definition of rigid designation may do the trick, if we restrict our attention to singular terms. If C is a context, then expression *D* is a *rigid designator with respect to C* iff: D is a singular term, and for all worlds W and W*, the referent of D with respect to C and W is identical with the referent of D with respect to C and W*. Kaplan could then be construed as saying that all (simple, singular term) indexicals are rigid designators with respect to all contexts.

12. Not all criticisms of Kaplan's theory concern belief and cognitive significance. As mentioned in section 2, various philosophers disagree with Kaplan's account of reference-fixing for demonstratives. Salmon 1989 criticizes the theory's assumption that propositions can vary in truth value from time to time. Braun 1995 criticizes the theory's (apparent) identification of character with an extensional function. Braun 1996 criticizes the theory's handling of multiple occurrences of demonstratives (see section 5.2 below).

13. We are assuming here that Kaplan's theory assigns contents to *utterances*. So, strictly speaking, we are considering the natural extension of Kaplan's theory to utterances that was presented in section 3.2.

14. Stalnaker's theory of indexical belief (Stalnaker 1981) relies heavily on a technical apparatus that is too elaborate to present here. But it is similar to Schiffer's, Chisholm's and Lewis's theories in one respect: it tries to "reduce" indexical belief to a more restricted class of "singular belief". In particular, Stalnaker tries to reduce indexical belief to belief in propositions about particular utterances or thinking-events. If *u* is Fred's utterance of (11), then Stalnaker would say that Fred's utterance expresses his belief in (very roughly) the proposition that the person who utters *u* is addressing exactly one person, who is wearing a business suit, and viewing exactly one person through a mirror, who is not. See Stalnaker 1981 for details, and Austin 1990 for critical discussion.

15. We are ignoring here any difficulties raised by contexts in which ‘that’ fails to refer.

16. Kaplan 1989a presents a second theory of demonstratives that does not use subscripted *that*s. On this theory (which he seems to prefer), occurrences of ‘that’ in English are represented by *dthat-terms* of the form "dthat[the F]". For details, see Kaplan 1989a. It turns out, however, that two dthat-terms can have different contents in a single context only if they have different characters. So the same problem arises for the dthat-term theory as for the subscripted ‘that’ theory.

Structured Propositions

It is a truism that two speakers can say the same thing by uttering different sentences, whether in the same or different languages. For example, when a German speaker utters the sentence ‘Schnee ist weiss’ and an English speaker utters the sentence ‘Snow is white’, they have said the same thing by uttering the sentences they did. Proponents of propositions hold that, speaking strictly, when speakers say the same thing by means of different declarative sentences, there is some (non-linguistic) thing, *a proposition*, that each has said. This proposition is said to be *expressed* by both of the sentences uttered (taken in the contexts of utterance -- to accommodate contextually sensitive expressions) by the speakers, and can be thought of as the information content of the sentences (taken in those contexts). The proposition is taken to be the thing that is in the first instance true or false. A declarative sentence is true or false derivatively, in virtue of expressing (in the context in which it is uttered -- I shall henceforth ignore contextual sensitivity and so dispense with qualifications of this sort) a true or false proposition.

Propositions are thought to perform a number of other functions in addition to being the primary bearers of truth and falsity and the things expressed by declarative sentences. When a German and English speaker believe the same thing, say that the earth is round, the thing they both believe is not a sentence but a proposition. For the English speaker would express her belief by means of the sentence ‘The earth is round’ and the German speaker would express her belief by means of the *different* sentence ‘Die Erde ist rund’. Thus when people believe, doubt and know things, it is propositions that they bear these cognitive relations to. Finally, it is the proposition a sentence expresses, and not the sentence itself, that possesses modal properties such as being necessary, possible or contingent.

That propositions perform these various functions is agreed upon by virtually all advocates of propositions. [1] There is considerably less agreement concerning the nature of the things, propositions, that perform these functions.

To say that propositions are *structured* is to say something about the nature of propositions. Roughly, to say that propositions are structured is to say that they are complex entities, entities having parts or constituents, where the constituents are bound together in a certain way. Thus, particular accounts of structured propositions can (and do) differ in at least two ways: 1) they can differ as to what sorts of things are the constituents of structured propositions; and 2) they can differ as to what binds these constituents together in a proposition. We shall discuss various accounts of structured propositions that differ in these ways below.

Put this way, the view that propositions are structured is purely a metaphysical thesis about what

propositions are like and entails nothing about the relation between a sentence and the proposition it expresses. But of course structured proposition theorists do have views about the relation between a sentence and the proposition it expresses.

---

1. Setting Up the Problems

Intuitively, given that a sentence expresses a structured proposition, the proposition will have parts or constituents that are the semantic values of words or subsentential complex linguistic expressions occurring in the sentence; and the proposition will have a structure similar to the structure of the sentence. For example, assuming that the semantic value of a name is its bearer and that the semantic value of a transitive verb is a relation, a structured proposition theorist will likely hold that the sentence

(1) Jason loves Patty

expresses a proposition consisting of Jason, the loving relation and Patty, bound together in some way into a unity. Letting '*j*' stand for Jason, '*p*' for Patty and '*L*' for the loving relation, we can represent the proposition in question as follows:

(1a) $[j[L[p]]]$

Thus (1a)'s structure is very close to that of (1); and (1a) has as constituents the semantic values of the words occurring in (1). Indeed, in the case of (1) and (1a), all and only semantic values of words in the sentence are constituents of the proposition. But a given account of structured propositions may not hold that this is the case in general for any one of at least three reasons. First, one might hold that certain words as they occur in phrases in sentences do not contribute *their* semantic values to the propositions expressed by those sentences because the semantic values of these words instead partially determine the semantic values of the *phrases* in which they occur, where these latter semantic values are contributed to the proposition. For example, one might hold that in the sentence

(2) Colin is a tall young man.

the phrase ‘is a tall young man’ contributes to the proposition expressed by (2) the property of being a tall young man, which is its semantic value. Thus, though the semantic value of the word ‘tall’ partly determines the semantic value of the phrase ‘is a tall young man’, the proposition expressed by (2) contains no constituent that is the semantic value of the word ‘tall’ alone. Second, one might hold that a sentence may express a proposition (in a context), where the proposition has constituents not contributed by *any* syntactic constituent of the sentence, let alone any word in the sentence. For example, Mark Crimmins [1992] claims that an utterance of the sentence

(3) It's raining

expresses a proposition to the effect that it is raining at a particular time and place. The present tense manages to somehow contribute the time of utterance to the proposition. But no syntactic constituent of the sentence contributes the place to the propositon, though Crimmins claims it is a constituent of the proposition expressed.[2] Third, one might hold that certain words simply have no semantic values, and so make no contribution to propositions. So-called neoplanastic ‘ne’ in French might be thought to be an example of this.

But even if, for one of the above reasons or some other reason, a sentence does not express a propositon whose constituents are *precisely* the semantic values of *words* in the sentence, we can still say that structured proposition theorists hold that sentences expresses propositions, where *many* (and likely most) constituents of the proposition are semantic values of words *or phrases* occurring in the sentence. So in the case of (1) and (1a), the constituents of the proposition are precisely the semantic values of the words in (1). In the case of (2) and (2a) (given the assumptions made above), the constituents of (2a) are precisely the semantic values of the name ‘Colin’ and and the verb phrase ‘is a tall young man’. And in the case of (3), the proposition it expresses has three constituents, two of which are contributed by ‘raining’ and the present tense construction.

Thus, ignoring, or at least not dwelling on, the qualifications just made, we can say that structured proposition theorists hold that sentences express propositions that are complex entities (most of) whose constituents are the semantic values of expressions occurring in the sentence, where these constituents are bound together by some structure inducing bond that renders the structure of the proposition similar to the structure of the sentence expressing it.

This highlights an important feature of structured proposition accounts that distinguishes them from the other main competing account of propositons, namely the account of propositions as sets of possible worlds (to be discussed below). Because structured propositions have as parts the semantic values of expressions in the sentences expressing them, the semantic values of those expressions are *recoverable* from the semantic values of the sentences (i.e. the propositions).

It is perhaps worth noting that one could have a theory according to which the semantic values of

expressions in a sentence are recoverable from the proposition expressed by the sentence, even though the semantic values of the expressions are not (mereological or set theoretic) parts of the proposition. For example, George Bealer [1993] formulates what he calls an *algebraic* conception of propositions (see also Bealer [1982]). Bealer associates with each propositon a "decomposition tree." This decompositon tree shows how a given proposition is the result of the application of logical operations to individuals, properties, relations or other propositions (e.g. the application of the logical operation of negation to a proposition P yields a proposition that is true iff P is false; the application of the logical operation of singular predication to an item and a property yields a proposition that is true iff the item possesses the property, etc.). In general, a sentence will express a proposition such that the semantic values of expressions in the sentence will occur on the decomposition tree associated with the proposition. Thus, the semantic values of expressions in a sentence will be recoverable from the proposition (together with its decomposition tree) expressed by the sentence. However, Bealer denies that these semantic values are in any sense set-theoretic members or mereological parts of the proposition. Bealer appears to hold that the propositon is metaphysically simple and has no parts at all. As the term is used here then, Bealer's is not an account of *structured propositions* for this reason. We will see below that others hold similar "algebraic" conceptions of propositions, where the propositions *are* complex entities consisting of constituents bound together in certain ways and so *are* structured propositions.

Since the structured proposition expressed by a sentence has a structure similar to that of the sentence and has as constituents semantic values of expressions occurring in the sentence, the theory of structured propositions allows for *distinct* necessarily equivalent propositions. For example, the propositions expressed by ‘Bachelors are unmarried’ and ‘Brothers are male siblings’ presumably are both necessarily true and hence are necessarily equivalent. But clearly the propositions expressed by these sentences have different constituents and so are distinct. The proposition expressed by the former presumbly contains the semantic value of ‘bachelor’ (perhaps, the property of being a bachelor), whereas the proposition expressed by the latter doesn't. And the proposition expressed by the latter contains the semantic value of ‘brother’, whereas the proposition expressed by the former doesn't. This is an important virtue of the structured proposition view. The fact that it has this feature and that its main competitor, the possible worlds account of propositions (discussed below), doesn't is one of the reasons many favor the structured proposition view.

In discussing recent accounts of structured propositions below, I shall highlight how, on those accounts, sentences that are necessarily equivalent may express distinct propositions; and how the semantic values of expressions in a sentence are recoverable from the proposition expressed by the sentence.

2. From Possible Worlds to Structured Propositions

Because the structured proposition view arose in large part due to dissatisfaction with the then prevailing view of propositions, discussing this other account of propositions will help to illuminate structured proposition views. The late 1950's and 1960's saw the development of a new sort of model theory, "possible worlds semantics", for systems of modal logic. In the framework of possible world semantics, linguistic expressions are assigned extensions "at" possible worlds. For example, names, *n*-place

predicates and sentences are assigned individuals, sets of *n*-tuples of individuals, and truth values, respectively, at different possible worlds. Intuitively, possible worlds are to be thought of as "ways things could have been", and the assignment of (possibly different) extensions to expressions at different possible worlds is part of capturing this intuition. Thus there might have been more or fewer cows, and this is reflected in the fact that the extension of ‘cow’ (intuitively, the set of things that are cows) can vary from possible world to possible world.

Because we wish the extensions of expressions to vary from possible world to possible world (at least in some cases), it is natural to associate with each expression a function from possible worlds to extensions appropriate to that sort of expression. Thus we associate with names, functions from possible worlds to individuals; with *n*-place predicates functions from possible worlds to sets of *n*-tuples; and with sentences, functions from possible worlds to truth values. Such functions from possible worlds to extensions of the appropriate sort are often called *intensions* of the expressions in question, and I shall use the term ‘intension’ this way throughout the present work[3] Now since most think that the extensions of sentences are truth values, as indicated above, the intension of a sentence is a function from possible worlds to truth values. Intuitively, it maps a world to the value *true* if the sentence is true at that world. Thus the intension of a sentence can be seen as the primary bearer of truth and falsity at a world: the sentence has the truth value it has at the world in virtue of its intension mapping that world to that truth value. Further, modal operators were typically construed as operating on the intensions of the sentences they embed, and so those intensions could plausibly be thought of as possessing modal properties. Since propositions were traditionally held to be the primary bearers of truth and falsity and the bearers of modal properties, it was natural for possible world semanticists to identify propositions with functions from possible worlds to truth values (sentential intensions), or equivalently, sets of possible worlds (the set of possible worlds at which the sentence in question is true). Indeed, this identification was thought by many to vindicate the previously mysterious notion of a proposition.[4] Possible worlds were apparently needed for the model theory of modal logic anyway; why not build propositions out of them?

Current structured proposition accounts arose largely out of dissatisfaction with the idea that propositions are sets of possible worlds (or functions from worlds to truth values). In fact, there were at least two quite distinct motivations for abandoning the view of propositions as sets of worlds and adopting the structured proposition account.

The first had to do with the way propositions are individuated on a possible worlds account. The view that propositions are sets of possible worlds does not individuate propositions very finely. For example, consider any pair of sentences that express metaphysically necessary propositions, say ‘Bachelors are unmarried’ and ‘Brothers are male siblings’. Since these propositions are true in all possible worlds, each must be the set of all possible worlds. But there is only one such set. Thus there is only such proposition! Hence these two sentences express the same proposition. (The view also predicts that all true sentences of mathematics express the same (necessary) proposition, that any two necessarily equivalent sentences express the same proposition, that the conjunction of any sentence *S* with a necessarily true sentence expresses the same proposition as *S*, and so on.)

This should make clear that the account of propositions as sets of worlds is not a structured proposition account. For, as we saw, on a structured proposition account, the semantic values of expressions in a sentence are recoverable from the proposition expressed by the sentence, since those semantic values are constituents of the proposition. This is why on such an account, ‘Bachelors are unmarried males’ and ‘Brothers are male siblings’ express distinct propositons: the propositions have different constituents. But on the possible worlds account, the property of being a bachelor is in no sense recoverable from or a constituent of the proposition expressed by ‘Bachelors are unmarried’. For the latter proposition is just the set of all possible worlds. How could the property of being a bachelor be "recovered" from this set? Similarly, the property of being a brother is not recoverable from the proposition expressed by ‘Brothers are male siblings.’ Again, the latter proposition is just the set of all possible worlds.

Further, if propositions are sets of possible worlds, belief is construed as a relation between individuals and propositions and a sentences of the form ‘*A* believes that *P*’ asserts that the individual *A* stands in the belief relation to the proposition expressed by ‘*P*’, then for any necessarily equivalent sentences ‘*P*’ and ‘*Q*’, ‘*A* believes that *P*’ and ‘*A* believes that *Q*’ cannot differ in truth value. This means that, for example, if ‘*A* believes that 1+1=2’ is true, so is ‘*A* believes that there is no greatest natural number’. These consequences of the view that propositions are sets of possible worlds were appreciated early on; and theorists made a variety of attempts to make these consequences seem less unpalatable. Despite these valiant efforts, many philosophers viewed these consequences as a sign that there was something very wrong with the view that propositions are sets of possible worlds. Thus, philosophers were open to an account of propositions that individuated propositions more finely than the possible worlds account. As we have seen, the structured proposition account is just such an account.

In order to make clear the second motivation for abandoning the view of propositions as sets of worlds and adopting the structured proposition account, we must discuss the notions of *rigid designation* and *direct reference*. A rigid designator is an expression that designates the same individual in all possible circumstances or worlds. In the early 1970's, Saul Kripke argued in *Naming and Necessity* that ordinary proper names are rigid designators. Kripke claimed that when we consider a sentence containing an ordinary proper name, such as

> Aristotle was a great philosopher

and ask whether it would have been true or false in various counterfactual circumstances, it is the properties of the very same man, Aristotle, in those circumstances that are relevant to the truth of the sentence. So, ‘Aristotle’ designates the same man in these various counterfactual circumstances; it is a rigid designator.

At around the same time, David Kaplan argued that indexicals (e.g. ‘I’, ‘here’, ‘now’) and demonstratives (e.g. ‘that’, ‘you’, ‘he’) are *directly referential*. Concerning directly referential expressions, Kaplan wrote:

> For me, the intuitive idea is not that of an expression which *turns out* to designate the same

> object in all possible circumstances, but an expression whose semantical *rules* provide *directly* that the referent in all possible circumstances is fixed to be the actual referent. In typical cases the semantical rules will do this only implicitly, by providing a way of determining the *actual* referent, and no way of determining any other propositional component. ([1977], p. 493)

Thus, a directly referential expression is a rigid designator: its associated semantic rules determine the actual referent of the expression (in a context) and when evaluating what is said by the sentence containing the expression (in that context) in other possible circumstances, this same referent is always relevant. To illustrate, if I utter

> I ski.

at the present time and we want to evaluate whether what I said by means of that utterance is true or false in other possible circumstances, it is *my* properties in those other circumstances that are relevant. Thus, 'I' is rigid: when evaluating the truth or falsity of what is said by an utterance of a sentence containing 'I' in counterfactual circumstances, it is the properties of the person whom 'I' referred to in the utterance (the actual utterer) that are relevant.

Kaplan intended to contrast directly referential expressions with expressions such as definite descriptions, which, though designating particular individuals, do so by means of descriptive conditions being expressed by the description and satisfied by the designated individual. Thus Kaplan wrote that directly referential expressions "refer directly without the mediation of Fregean *Sinn* as meaning". ([1977], p. 483) The designation of definite descriptions *is* mediated by something like a Fregean sense (i.e. their associated descriptive conditions).

Of course, even if descriptions are not directly referential, some are rigid designators. For example, 'the successor of 1' designates the same individual (namely, the number 2) in all possible worlds. So, though all directly referential expressions are rigid designators, some rigid designators are not directly referential. As was mentioned above, in a possible worlds semantics linguistic expressions are associated with intensions, functions from possible worlds to appropriate extensions. In the case of expressions designating individuals, these intensions will be functions from possible worlds to individuals. Note that *all* rigid designators (whether directly referential or not) will have intensions that are constant functions: they will be functions that map all possible worlds to the same individual. Thus possible worlds semantics tends to blur the distinction between directly referential expressions and rigid non-directly referential expressions (e.g. rigid definite descriptions). To make the distinction between directly referential expressions and rigid non-directly referential expressions more vivid, Kaplan invoked the notion of structured propositions:

> If I may wax metaphysical in order to fix an image, let us think of the vehicles of evaluation -- the what-is-said in a given context -- as propositions. Don't think of propositions as sets of possible worlds, but rather as structured entities looking something

> like the sentences which express them. For each occurrence of a singular term in a sentence there will be a corresponding constituent in the proposition expressed. The constituent of the proposition determines, for each circumstance of evaluation, the object relevant to evaluating the proposition in that circumstance. In general the constituent of the proposition will be some sort of logical complex, constructed from various attributes by logical composition. But in the case of a singular term which is directly referential, the constituent of the proposition is just the object itself. Thus it is that it does not just *turn out* that the constituent determines the same object in every circumstance, the constituent (corresponding to a rigid designator) just *is* the object. *There is no determining to do at all*. On this picture -- and this is *really* a picture and not a theory -- the definite description
>
> (1) The n[(snow is slight & n^2=9) $\vee$ (~snow is slight & 2^2=n+1)]
>
> would yield a constituent which is complex although it would determine the same object in all circumstances. Thus, (1), though a rigid designator, is not directly referential from this (metaphysical) point of view. ([1977], pp. 494-495)

(Kaplan goes on to attribute this "metaphysical picture" of structured propositions to Russell.) Adopting this structured proposition account makes it simple to distinguish between directly referential expressions and other expressions, rigid or not. Directly referential expressions contribute their *referents* (in a context) to the propositions expressed (in that context) by the sentences containing them. Non-directly referential expressions contribute some complex that may or may not determine the same individual in all possible circumstances. Thus the desire to distinguish clearly between directly referential expressions and other rigid designators prompted Kaplan to re-introduce the Russellian notion of a structured proposition into the philosophical literature (see the discussion of Russell below). However, in [1977], Kaplan tends to treat the notion of a structured proposition as a heuristic device. He repeatedly calls it a picture, explicitly says that it is not part of his theory, and in his formal semantics he adopts the possible worlds account of propositions (contents of formulae), taking them to be functions from worlds (and times) to truth values.

Many current direct reference theorists take the structured proposition account much more seriously. It *is* part of *their* theory in the sense that when they say that an expression is directly referential they are *literally* saying that it contributes its referent to propositions expressed by sentences containing it, (e.g. see the discussion of Salmon and Soames below).

3. Some Recent Accounts of Structured Propositions

Having discussed structured proposition accounts in a general way, the best way to further illuminate these accounts of propositions is to discuss some recent work on structured propositions. In so doing, we shall see various respects in which accounts of structured propositions can differ. Three caveats before

proceeding. First, I mentioned above that structured proposition accounts, unlike possible world accounts of propositions, allow for distinct necessarily equivalent propositions, and thus individuate propositions more finely than possible worlds accounts. There are other accounts of propositions, or things that are intended to do the work of propositions, that are not structured proposition accounts (given the way that term is used here), but that allow for distinct necessarily equivalent propositions or things that are to do the work of propositions. I already mentioned the example of Bealer [1993]. Another example is the *interpreted logical form* account defended by Larson and Ludlow [1993]. Though such accounts will not be discussed here, the reader should be aware of them and that they are motivated by many of the considerations that motivate structured proposition theorists. In particular, they attempt to individuate propositions (or things that do the work of propositions) more finely than possible worlds accounts of propositions. Second, in discussing a sampling of recent work on the view that propositions are structured, I do not intend to exhaust the versions of structured proposition approaches that there are. Rather, I intend to highlight some of the main issues and current approaches. To that end, I shall discuss three broad approaches to structured propositions. I call these the *Neo-Russellian Approach*, the *Structured Intensions Approach*, and the *Algebraic Approach*. In discussing each approach, I shall mention a number of authors who adopt the approach, but for definiteness I shall concentrate primarily on a representative of that approach in explaining it. The reader should be aware that these groupings are somewhat loose, and that there may be important differences between authors who are grouped together. Third, though I shall here and there raise questions, I shall not try here to criticize the various approaches I discuss. I view my task as that of introducing the reader to approaches to structured propositions. The task of criticizing the various apporaches is a task for another day. I begin with the neo-Russellian approach.

The Neo-Russellian Approach

In a series of papers and a book, Scott Soames [1985, 1987, 1989] and Nathan Salmon [1986a, 1986b, 1989a, 1989b] have laid out what is probably the best known current theory of structured propositons. There are some differences of detail between Salmon and Soames, but I shall treat them here as holding the same view. Though I shall discuss some of their contributions separately, I shall follow the account of structured propositions laid out in Soames [1987].

First, Soames [1985,1987] produced what many take to be a devastating attack on the view of propositions as sets of possible worlds. Soames showed that even when one tries to get more fine-grained propositions-as-sets-of-worlds by allowing metaphysically impossible worlds (e.g. worlds in which George Bush is identical with Ronald Reagan), inconsistent worlds (in which a thing can both possess and lack a property), and incomplete worlds (where some purported "matters of fact" are simply not settled), the resulting view, when combined with other independently plausible assumptions, is riddled with overwhelming difficulties. These difficulties all stem from the fact, noted earlier, that on the worlds view, sentences with very different syntactic structures and containing words with different semantic values may express the same proposition. Soames [1987] concludes that we ought to give up the view that propositions are sets of worlds of any sort, and embrace an account of propositions according to which propositions are structured entities, with individuals, properties and relations as constituents.

Soames called these *structured Russellian propositions*. If the syntactic structures of sentences and the semantic values of words occurring in them are reflected in the structures and constituents of propositions they express, sentences with different syntactic structures and containing words with different semantic values, whether true in all the same worlds or not, may express different propositions. It is perhaps worth noting that having sentences with different syntactic structures and containing words with different semantic values express different propositions doesn't *require* one to hold that propositions themselves are structured and contain the semantic values of the words as constituents. Still, it is a natural way of accounting for why sentences with different syntactic structures and containing words with different semantic values that are true in all the same worlds express different propositions. Soames [1987] sketches a formal theory of structured propositions, including an assignment of structured propositions to the sentences of a simple formal language, and a definition of *truth relative to a circumstance* for structured propositions.

Soames and Salmon are direct reference theorists, holding that names (as well as indexicals and demonstratives) have their referents as their semantic values and so contribute them to the propositions expressed by sentences containing them. Further they hold that predicates and intransitive verbs have properties as their semantic values; and that transitive verbs have relations as their semantic values. Thus they hold that sentences such as

(4) Scott runs.

(5) Scott saw Nathan.

express the propositions

(4a) $<<o>, R>$

(5a) $<<o,o'>,S>$

where o is Scott, o' is Nathan, R is the property of running, and S is the relation of seeing. The negation of (4) expresses the proposition

(4b) $<\mathrm{NEG}, <<o>, R>>$

where NEG is the truth function for negation. And the conjunction of (4) and (5) (in that order) expresses the proposition

(5b) $<\mathrm{CONJ}< <<o>, R>, <<o,o' >,S>>>$

where CONJ is the truth function for conjunction. Similar remarks apply to sentences formed with other truth functional connectives. Further a sentence such as

Something runs.

expresses the proposition

(6a) <SOME, *g*>

where SOME is the property of being a nonempty set and *g* is the function from individuals *o*′ to the proposition <<*o*′>,*R*>, (where, as before, *R* is the property of running).

It should be easy to imagine the definition of *truth relative to a circumstance* for structured propositions of the sort mentioned above. For example, (5a) will be true at a circumstance *c* iff <*o*,*o*′> is in the extension of the relation *S* at *c*. (5b) will be true at *c* iff CONJ maps the truth values of <<*o*>, *R*> and <<,*o*,*o* ′>,*S*> at *c* to truth. And (6a) will be true at *c* iff there is an individual in *c* that *g* maps to a proposition that is true in *c*, (in that case the set of individuals in *c* that *g* maps to propositions true in *c* possesses SOME).

It should be clear that on this account of propositions sentences that are necessarily equivalent may express distinct propositions, and that the semantic values of expressions in a sentence are recoverable from the proposition it expresses. For example, ‘All bachelors are unmarried’ and ‘All brother are male’ are both true in all possible worlds. But on the present view, the former expresses a proposition that has as a constituent a propositional function mapping an object to the proposition that that object is unmarried; the latter does not. Further, e.g. the semantic value of ‘runs’ as it occurs in sentence (4) is recoverable from the proposition (4) expresses in that it is a constituent of that proposition. Similar remarks apply to 5/5a and 6/6a (except that in 6a the semantic value of ‘runs’ is encoded in *g*: that is, *g* maps individuals o to the proposition that *o* runs, which in turn has the semantic value of ‘runs’ as a constituent).

Note that this account of propositions (including the commitment to names being directly referential) entails that sentences that differ only with respect to coreferential names express the same proposition. Thus

Mark Twain is Samuel Clemens.

and

Samuel Clemens is Samuel Clemens.

express the same proposition on this view. Many have found this result incredible, since it would appear that the one sentence could be informative and the other not. Salmon and Soames also hold that ‘believes’ expresses a relation between individuals and propositions, so that ‘Scott believes that Mark Twain is Samuel Clemens’ expresses a proposition to the effect Scott stands in the believes relation to the propositon expressed by ‘Mark Twain is Samuel Clemens’. But then it follows that ‘Scott believes

that Mark Twain is Samuel Clemens' and 'Scott believes that Samuel Clemens is Samuel Clemens' express the same proposition (since the embedded sentences in both belief ascriptions express the same proposition) and so cannot diverge in truth value. Many have found this consequence of the Salmon-Soames view of propositions (and belief ascriptions) hard to swallow as well.

Salmon [1986] is largely an extended defense of these two consequences of the Salmon-Soames view. It is beyond the scope of the present work to explain Salmon's defense and the interested reader should consult that work directly.[5]

In the formal semantics offered by Salmon and Soames, propositions are ordered *n*-tuples (or concatenations of *n*-tuples), as are (4a), (5a), (5b) etc. above. But since Salmon and Soames say nothing explicitly about what holds propositions together, it is unclear whether these *n*-tuples and concatenations merely *represent* propositions in the formalism, or whether Soames and Salmon take them *to be* propositions. If the former, then the Salmon and Soames view is incomplete and we need to be told what propositions really are, and more specifically what it is that really holds propositions together (i.e. what the corner brackets in (4a), (5a) etc. stand for). If the latter, then the view at least seems to have trouble accounting for some of the properties possessed by propositions. Propositions have truth conditions: they are true or false, depending on how the world is. So if some ordered *n*-tuples are propositions, some ordered *n*-tuples have truth conditions. But ordered *n*-tuples don't seem to be the kinds of things that have truth conditions. Indeed, presumably many ordered *n*-tuples have no truth conditions, (e.g. <1,2,3>). So how/why did those *n*-tuples that are propositions come to have truth conditions? Similar remarks apply to modal properties. Propositions are necessary, contingent, and possible. These, again, don't seem to be properties of *n*-tuples. Finally, if propositions are ordered *n*-tuples, that is, set theoretic constructions, it is hard to see why a *particular* set theoretic construction is the proposition in question (and so has truth conditions, modal properties, etc.) as opposed to some other set theoretic construction that seems equally well suited to the task.[6] For example, we said that the sentence

> (4) Scott runs.

expresses the proposition/set theoretic construction

> (4a) <<*o*>, *R*>

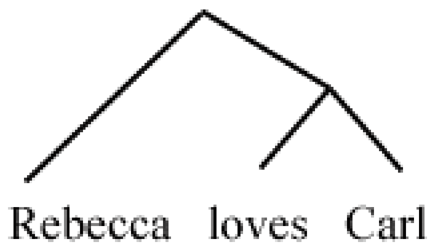
But the following set theoretic construction seems equally suited to be the proposition (4) expresses:

> (4b) <*R*, <*o*>>

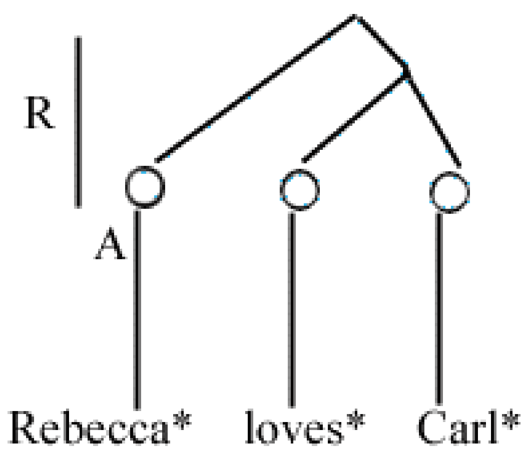
So why it is that (4a), instead of (4b), is the proposition (4) expresses, and has modal properties and truth conditions?

This question as to what holds structured propositions together and gives them their structure turns us to other recent work within the neo-Russellian approach. While adopting more or less the same view as

Salmon and Soames on the semantic values of different kind of words (though claiming to be strictly neutral on the question of what the semantic values of names and predicates are), Jeffrey C. King [1994, 1995, 1996] develops a view as to what binds the constituents of propositions together. He holds that propositions are *not n*-tuples and that a complex relation binds together the constituents of a proposition and provides the proposition with its structure. In order to explain what complex relation binds the constituents together, let us consider the sentence ‘Rebecca loves Carl’ in "tree form":



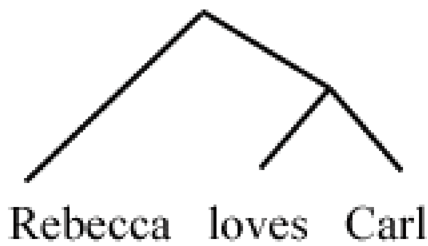
The tree represents the syntactical relation binding together the words in the sentence. We shall call this the *sentential relation* of the sentence. The words in the sentence, of course, bear semantic relations to things in the world, their semantic values (or s.v.'s): the s.v. of ‘Rebecca’ is Rebecca; the s.v. of ‘loves’ is the relation of loving; and the s.v. of ‘Carl’ is Carl. The crucial point is that since the words stand in a sentential relation in the sentence, and the words in the sentence stand in semantic relations to the s.v.'s, the s.v.'s themselves stand in the relation resulting from composing the sentential relation of the sentence with the semantic relations the words in the sentence bear to their s.v.'s, while existentially generalizing over the words. We can represent the relation the s.v.'s stand in thus:



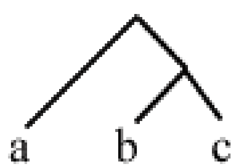
where Rebecca*, loves* and Carl* are the s.v.'s of ‘Rebecca’, ‘loves’ and ‘Carl’; the portion of the diagram labeled *R* is the sentential relation binding together the words in the sentence above; the circles at the terminal nodes of this relation represent that the words have been existentially generalized away; and the lines from the circles to the s.v.'s represent the semantic relations obtaining between ‘Rebecca’ and Rebecca* (i.e. Rebecca), etc. Thus, for example, *A* is presumably the reference relation that obtains between ‘Rebecca’ and Rebecca*. On King's view, then, the proposition expressed by ‘Rebecca loves

Carl' *is* the above: namely, the s.v.'s of the words in this sentence standing in the complex relation that is the result of composing the sentential relation of the sentence with the semantic relations the words bear to their s.v.'s, existentially generalizing away the words. Thus the relation that holds together the constituents of the proposition is literally "built out of " the sentential relation and the semantic relations words bear to their s.v.'s.

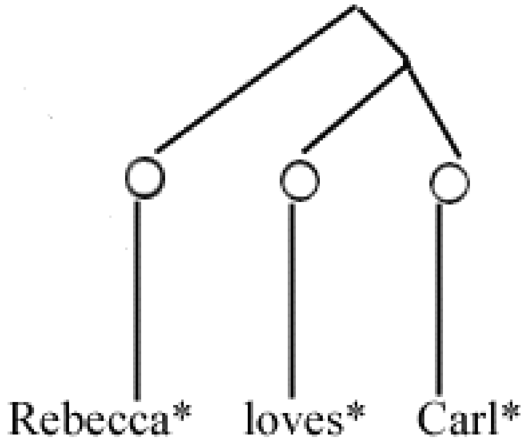
This view of what holds the constituents of propositions together has at least three virtues. First, it "builds" the relations binding together constituents of propositions out of relations (sentential relations binding together words in sentences; and semantic relations between words and their s.v.'s) that we are already committed to. Second, and related to this, it leaves little room for doubt that propositions exist. For from the fact that there is a sentence 'Rebecca loves Carl', which in tree form looks as follows:



Where 'Rebecca' bears a semantic relation to Rebecca, 'loves' bears a semantic relation to the relation of loving, and 'Carl bears a semantic relation to Carl, it follows that Rebecca, the relation of loving and Carl stand in the relation of there being lexical items *a*, *b* and *c* occurring in a sentence in which they stand in the following relation:



such that Rebecca is the s.v. of *a*, the relation of loving is the s.v. of *b*, and Carl is the s.v. of *c*. In other words, it follows that the following entity exists:



But this entity just is our proposition! Thus, given very minimal, quite uncontentious assumptions, it follows that propositions exist on this view. So even philosophers with rather strict naturalistic scruples will have to admit that propositions as they are construed on the present view exist. Third, the view can explain why propositions are the sorts of things that represent or have truth conditions. I refer the interested reader to King [1995] for this explanation.

The Structured Intensions Approach

Having seen the main features of neo-Russellian approaches, let us turn to structured meaning accounts. The roots of these accounts can be traced to Rudolf Carnap [1947], and his notion of intensional isomorphism. David Lewis [1972] and Max Cresswell [1985] have worked out similar, detailed versions of the structured meanings approach, though there are important differences in their views. I shall here discuss Cresswell's [1985] version of the view.[7] Because our concern is with conceptions of structured propositions, there are many features of Cresswell [1985] that I shall not discuss (e.g. I shall not desribe Cresswell's account of the semantics of verbs of propositional attitude).

Both Lewis [1972] and Cresswell [1985] are motivated by some of the same considerations that motivated neo-Russellians like Salmon and Soames. Lewis and Cresswell both wish to find a more fine grained "semantic value" for sentences than functions from worlds (or, as in Lewis [1972], *indices*) to truth values or, equivalently, sets of worlds. For example, Cresswell [1985] claims that verbs of propositional attitude are (sometimes) sensitive to more than the intensions (functions from worlds/indices to truth values) of the sentences they embed. Thus Cresswell claims that

> ...one might easily have two sentences α and β that are true in exactly the same worlds and yet are such that
>
> > x φs that α
>
> is true, but

x φs that β

is false.
[p. 73; φ here is a propositional attitude verb such as ‘believe’.]

Thus Cresswell wishes to associate with a sentence (or more accurately, a ‘that’ clause) some semantic value that is more fine grained than a set of worlds, so that attitude verbs may (sometimes) distinguish between sentences that are true in exactly the same worlds. Strictly, Cresswell holds that sometimes attitude verbs are sensitive only to the sets of worlds in which the sentences they embed are true (i.e. their intensions); but sometimes attitude verbs are sensitive to more than this. In these latter cases, Cresswell wishes to asscociate a semantic value more fine grained than a set of worlds with the embedded sentence (or ‘that’ clause). Cresswell accomplishes this by holding that ‘that’ in English attaches to a sentence to form a name, and that ‘that’ in this role is highly ambiguous. In one of its meanings, ‘that’ attaches to a sentence and forms a name of the intension of the sentence (i.e. the set of worlds in which it is true).[8] In such cases, the attitude verb is sensitive only to the intension named by the ‘that’ clause following it. However, ‘that’ has another meaning on which it combines with a sentence to form the name of a much more fine-grained entity (in the sense that sentences true in all the same worlds may be associated with different fine-grained entities). In such cases, verbs of attitude are sensitive to differences in these fine-grained entities. Since our concern is with structured propositions, or with semantic values of sentences more fine grained than sets of worlds, I shall henceforth focus on Cresswell's account of these fine-grained entities named by *some* ‘that’ clauses.[9] Henceforth, then, when I talk about the fine grained entity *associated with* a sentence or ‘that’ clause on Cresswell's view, I should be understood as talking about what a ‘that’ clause containing the sentence names, given that the meaning of ‘that’ in the ‘that’ clause is the one that when combined with the sentence yields a name of the most fine grained entity named by any ‘that’ clause in which the sentence occurs. This is important to bear in mind, since for Cresswell, strictly speaking, a sentence not in a ‘that’ clause does not express this fine grained entity.

Consider the sentence

(7) Max runs.

For Cresswell, the meaning of a predicate like ‘runs’ is essentially its intension: a function from individuals to sets of worlds (it maps an individual to the worlds at which she runs).[10] Let I_r be this intension. The meaning of a name like ‘Max’ (in some cases at least) is simply its referent: *o*. Thus, the fine grained entity associated with (7) is the ordered pair:

(7a) $<o,I_r>$

The negation of (7) will be associated with the following:

(7b) $<NOT,<o,I_r>>$

where NOT is the function from sets of worlds to sets of worlds that maps a set of worlds to its complement.

Finally, the sentence:

(8) Someone runs.

is associated with

(8a) $<\Sigma,I_r>$

where Σ is the function *from* functions from individuals to sets of worlds *to* sets of worlds such that $\Sigma(f) = \{w$: for some o, w is in $f(o)\}$.

It should be clear that, as on the neo-Russellian approach, sentences that are true in all the same worlds may be associated with different fine grained entities of the sort posited by Cresswell. For example, even if ‘All brothers are siblings’ and ‘All bachelors are male’ are true in exactly the same worlds, the fine grained entity associated with the latter will contain the meaning (function from individuals to sets of worlds) of ‘male’ and the fine grained entity associated with the former will not. It should also be clear that the semantic values of expressions are recoverable from the propositions expressed by sentences containing them. For example, the semantic value of ‘runs’ as it occurs in (7) is a constituent of the fine-grained entity expressed by (7) (i.e. (7a)). Similar remarks apply to (7b) and (8a).

A final remark about Cresswell's view is in order. The fine-grained entities we have been discussing are what verbs of propositional attitude are sensitive to when they are sensitive to more than the intension/set of worlds associated with a sentence they embed. However, they do not seem to be the primary bearers of truth for Cresswell. For Cresswell, each sentence is associated with a set of worlds/intension, which Cresswell calls a *proposition*; and the truth or falsity of a sentence at a world is determined by what proposition it expresses. So these seem to be the primary bearers of truth and falsity for Cresswell.[11] Thus, it appears that for Cresswell, in contrast to the neo-Russellians, the primary bearers of truth and falsity and the fine grained entities associated with the sentences (or ‘that’ clauses) that verbs of attitude embed and to which they are (sometimes) sensitive are different.

The Algebraic Approach

Finally, I turn to algebraic approaches. Above, I mentioned the view of Bealer [1982]. Though Bealer in some sense adopts an algebraic approach to propositions (see the above discussion), as mentioned above he apparently holds that propositions have no (set theoretic or mereological) parts, and so doesn't count as a structured proposition theorist in the sense in which the term is used here. Thus, I will consider here

adherents to the algebraic approach who do hold that the propositions yielded by their algebras are complex and have "parts". Aside from Bealer [1979, 1982 and 1993], work in this tradition includes Edward Zalta [1983 and 1988], and Christopher Menzel [1986 and 1993]. I shall focus here on the formulations in Zalta [1988]. Though Zalta has an extensive, axiomatized theory of propositions, and ordinary and abstract individuals, properties, and relations, we confine our attention here to his view about propositions. Still, since Zalta views propositions as zero-place relations, we will say something about his views on properties and relations.

Advocates of the algebraic approach such as Zalta, like the neo-Russellians and the advocates of structured meaning approaches, think that a good theory of propositions must allow for distinct, necessarily equivalent propositions. Thus, he writes:

> Necessarily equivalent propositions may be distinct. If the theory of propositions is not fine-grained enough to distinguish necessarily equivalent propositions, the ability to accurately represent belief is lost. [Zalta 1988, p. 57]

To appreciate how Zalta achieves the goal of having a fine-grained theory of propositions, we begin by discussing how he views relations generally, since, as just mentioned, Zalta takes propositions to be zero-place relations (and properties to be one-place relations). Zalta holds that relations are "primitive entities", by which he means that they are not to be explained or "defined" in terms of other entities/notions. But at least some relations are complex. For example, if we take a two-place relation (between objects) *Rxy* and "plug" one of its argument places with the object *b*, we get the one-place relation (property) *Rxb* ("bearing *R* to *b*").[12] This one-place relation is complex, having *b* and *R* as parts. Similarly, if we take a three-place relation *Sxyz* and "universalize" the third argument position, we get a two place relation that we might represent thus: $(\forall z)Sxyz$ ("*x* and *y* (in that order) stand in *S* to everything"). Here again, the two-place relation is complex, having *S* and (something corresponding to) "universalization" as parts. Zalta's idea is that properties, relations and individuals can be "harnessed together" to form new, complex relations. In his axiomatized theory of relations, Zalta introduces a comprehension schema for relations (see Relations, p. 46) that insures that all manner of complex relations will be available. To insure that all instances of the comprehension schema are true in all interpretations of his axiomatized theory, Zalta has these interpretations include the following group of "logical functions": PLUG_i, NEG, COND, UNIV_i, $\text{REFL}_{i,j}$ $\text{CONV}_{i,j}$, VAC_i, NEC, WAS and WILL. Roughly (and suppressing reference to worlds and times) PLUG_i is a function that maps an *n*-place relation *R* and an object *b* to the $n-1$ place relation R' such that $\langle o_1,...,o_{i-1}, o_{i+1},...,o_n\rangle$ stand in R' iff $\langle o_1,...,o_{i-1}, b, o_{i+1},..., o_n\rangle$ stand in *R*. NEG is a function that maps an *n*-place relation *R* to an *n*-place relation R' such that *n* things stand in R' iff they don't stand in *R*.[13] Thus the repeated application of these functions yields appropriate relations to make true the instances of Zalta's comprehension schema for relations. For example, consider the following two instances of his comprehension schema (where ‘F’ is a variable ranging over one-place relations; ‘*b*’ is a name of an individual; and the other predicate letters are constants and so name particular relations):[14]

$(\exists F)(Fx \text{ iff } Rxb)$

(∃*F*)(*Fx* iff ~*Px*)

If we apply PLUG_2 to the individual denoted by '*b*' and the (two-place) relation denoted by '*R*', we get a one-place relation that makes the first instance of the schema true; and if we apply NEG to the denotation of '*P*', we get a one-place relation that makes the second instance true.

As we have mentioned, propositions are zero-place relations for Zalta. Thus, PLUG_i and the rest of the "logical functions" mentioned above can be applied to various entities to yield propositions. Thus the proposition expressed by a sentence like

Ed runs.

is the result of applying the PLUG_1 function to the property of running and Ed. This proposition consists of Ed saturating the one argument place of the running property. Similarly, a sentence like

Ed does not run.

expresses the proposition that is the result of applying PLUG_1 to running and Ed as before, and then applying NEG to the output of PLUG_1. Finally, a sentence like

Everything runs.

expresses the result of applying UNIV_1 to the property of running. This idea that there is some group of "logical functions" whose repeated application to some other entities yield complex propositions (and relations) is characteristic of what I am calling algebraic approaches.

It should be clear that necessarily equivalent sentences may express distinct propositions on Zalta's view. For example, the sentences 'All brother are male siblings' and 'All bachelors are unmarried' express propositions that are true in all possible worlds. But the first expresses a proposition that results from applying COND to the properties of being a brother and being a male sibling, and applying $\text{REFL}_{1,2}$ and then UNIV_1 to the output of COND. The second does not, but instead results from applying these functions in the same order to the properties of being a bachelor and being unmarried. Further, it should be clear that the semantic values of expressions are recoverable from the propositions expressed by sentences in which they occur. E.g. both Ed and the property of running, which are the semantic values of 'Ed' and 'runs', are constituents of the proposition that Ed runs, which is expressed by 'Ed runs', since this proposition consists of Ed saturating the one argument place in the property of running.

Having sketched Zalta's view of propositions it is worth mentioning a couple points about it. At least in some cases, what binds together the constituents of a proposition is in some sense "built into" one of the

constituents of the proposition for Zalta, (as we shall see below, the same is true for Frege and Russell). Consider again the sentence:

> Ed runs.

Recall that this sentence expresses the proposition that results from applying $PLUG_1$ to Ed and the property of running. The output is Ed saturating ("plugged into") the one argument place of the property of running. There are two things to notice about this proposal. First, it is one of the constituents of the proposition, the running property, that binds the constituents of the proposition together. The proposition is held together in virtue of Ed "plugging" the one argument place in the running property. Second, the proposition *just is* Ed "plugging"/possessing that property!

Such a view immediately raises a worry about false propositions (discussed below in connection with Russell's POM account of propositions). For one might argue as follows. Suppose Ed doesn't run. Then Ed doesn't plug/saturate the one argument place in the property of running (i.e. doesn't possess this property). But Ed possessing the running property *just is* the proposition that Ed runs. Thus there is no proposition that Ed runs. Similar reasoning shows that any other false proposition fails to exist. So there are no false propositions.

Obviously, Zalta does not want to be saddled with this result, and he isn't. He holds that the even if Ed doesn't run, there is a proposition consisting of Ed saturating the argument place in the running property. That proposition simply isn't true. But the proposition consists of Ed plugging the property if running. For Ed to do this is simply different from Ed exemplifying or possessing that property, which is what happens when the proposition is true. It is in the nature of the running property to be "plugged" by things like Ed, to form the proposition that Ed runs. And it is also in its nature to allow Ed to exemplify it, in which case the result of plugging Ed into the property of running is true. This makes it sound as though the complex consisting of Ed exemplifying running makes true the proposition consisting of Ed plugging running. However, Zalta appears to deny this when he says:

> The metaphysical truth or falsity of these logical complexes [propositions] is basic. If a proposition is true, there is nothing else that "makes it true". Its being true is just the way things are (arranged). ([1988], p. 56)

Finally, though we shall not go into it here, it is worth mentioning that when Zalta gets to the semantics of verbs of propositional attitudes, it is not only the propositions considered thus far that are objects of the attitudes and make belief ascriptions true or false. Zalta ends up claiming that sentences embedded with respect to attitude verbs are ambiguous, sometimes expressing the sorts of propositions we are discussing, and sometimes expressing other propositions that instead of containing the individuals, properties and relations thus far discussed, contain *senses* of these individuals, properties and relations. These senses are "abstract" individuals and relations, instead of the ordinary individuals and relations discussed thus far. Hence Zalta ends up with a theory of belief ascriptions that invokes both fine-grained propositions and neo-Fregean senses. The interested reader should consult Zalta [1988].

4. Historical Antecedents to Current Views: Frege

As with many ideas discussed in contemporary philosophy of language, the idea that propositions are structured is present in Gottlob Frege's writings. Frege had a view both about the constituents of structured propositions and about what held these constituents together in the proposition. Frege held that simple linguistic expressions are associated with entities he called *senses*. Though there is some controversy about precisely how to understand the notion of sense, Frege explicitly distinguishes the sense of a linguistic expression from both the subjective ideas speakers associate with the expression and the thing in the world the expression "stands for". Further, the sense of an expression determines what thing in the world the expression stands for. Thus the sense of a proper name such as ‘Ronald Reagan’ must be distinguished from any subjective ideas speakers associate with the name (e.g. feelings of anger, fondness, etc.) and from Reagan himself. And the sense of the name "picks out" Reagan as the thing in the world the name stands for. It may help to think of the sense as some descriptive condition satisfied uniquely by Reagan (and not to think any more about what is meant by a *descriptive condition*). Complex linguistic expressions are also associated with senses. And Frege held that the sense of a complex expression is a function of the senses of its simple parts and how they are put together. Frege called propositions *thoughts* (*Gedanken*), and held that the thought/proposition expressed by a sentence is itself a sense. And, like the senses of other complex linguistic expressions, the proposition/thought expressed by a sentence is a function of the senses of the words in the sentence and how they are put together. Now Frege at least sometimes appears to hold the stronger view that the sense of a sentence (proposition/thought) *has as constituents* the senses of the words in the sentence. And as the following quotation shows, his account of how these sense-constituents are held together in the proposition/thought depends on different kinds of linguistic expressions having different kinds of senses:

> For not all parts of a thought can be complete; at least one must be ‘unsaturated’, or predicative; otherwise they would not hold together. For example, the sense of the phrase ‘the number 2’ does not hold together with that of the expression ‘the concept *prime number*’ without a link. We apply such a link in the sentence ‘the number 2 falls under the concept *prime number*’; it is contained in the words ‘falls under’, which need to be completed in two ways -- by a subject and an accusative; and only because their sense is thus ‘unsaturated’ are they capable of serving as a link. ([1892], p. 54)

Remarks like this suggest that Frege's view was that propositions are complex entities whose parts are other senses. The proposition is held together in virtue of the fact that at least one of the senses is unsaturated (Frege sometimes also says predicative, or in need of supplementation). The complete or saturated senses "saturate" or complete the unsaturated senses and in so doing are bound to them to form the proposition/thought. Thus, on this way of interpreting Frege, the mechanism for binding together the constituents of a structured proposition is built right into some of the constituents. (Recall that this was true of the view of Zalta [1988] as well.)

5. Historical Antecedents to Current Views: Russell

Bertrand Russell, to whom many current structured propositions theorists attribute the idea of structured propositions, held various views about the nature of propositions over the course of his career. However, the account of propositions held by Russell that is thought by many to be the progenitor of current accounts of structured propositions is the one Russell defended in *Principles of Mathematics* (Russell [1903]). We shall confine our attention to that account here. Russell differed with Frege both on what the constituents of structured propositions are and on what binds them together in the proposition. Russell uses the word ‘term’ for constituents of propositions. Thus he writes:

> Whatever may be an object of thought, or may occur in any true or false proposition ...I call a *term*. ...A man, a moment, a number, a class, a relation, a chimaera, or anything else that can be mentioned, is sure to be a term; and to deny that such and such a thing is a term must always be false. ([1903], p. 43)

Thus we already see that Russell differs from Frege on what kinds of things can be constituents of propositions. For Frege, all constituents of propositions are senses. For Russell, a man or a mountain can be a constituent of a proposition. In a now famous correspondence between Frege and Russell, Frege asserted that the sense of the name ‘Mont Blanc’, and not Mont Blanc itself "with all its snowfields", occurs in the proposition/thought that Mont Blanc is 4,000 meters high. Russell replied by saying:

> I believe that in spite of all its snowfields Mont Blanc itself is a component part of what is actually asserted in the proposition ‘Mont Blanc is more than 4,000 metres high’. (reprinted in Gabriel, *et al.*, [1980], p. 169)

Russell goes on to distinguish two kinds of terms or propositional constituents:

> Among terms, it is possible to distinguish two kinds, which I shall call respectively *things* and *concepts*. The former are the terms indicated by proper names, the latter those indicated by all other words. ([1903], p. 44)

So for Russell, all propositional constituents are things or concepts. On Russell's view, a sentence such as:

> Socrates is human

expresses a proposition with three constituents, corresponding to the three words in the sentence. Socrates himself is one of the constituents, the other two constituents being the concepts contributed by ‘is’ and ‘human’.

Having seen that Russell held different kinds of things to be constituents of propositions than did Frege, we shall turn to his views on what binds together the constituents of structured propositions. Russell appears to hold that the propositional contributions of verbs (which contributions Russell often calls

verbs) hold together the constituents of propositions. Thus he writes:

> Consider, for example, the proposition 'A differs from B'. The constituents of this proposition, if we analyze it, appear to be only *A*, difference, *B*. Yet these constituents, thus placed side by side, do not reconstitute the proposition. The difference which occurs in the proposition actually relates *A* and *B*, whereas the difference after analysis is a notion which has no connection with *A* and *B*. ([1903], p. 49)

And later Russell writes:

> Owing to the way in which the verb [propositional contribution of a verb] actually relates the terms of a proposition, every proposition has a unity which renders it distinct from the sum of its constituents. ([1903], p. 52)

Russell's idea that a proposition is something beyond the sum of its constituents certainly seems correct. The collection, or mereological sum, of *A*, difference and *B* is not the proposition that *A* differs from *B*. Different propositions may have the same Russellian constituents, as with the propositions expressed by the following sentence pair:

> Jason loves Patti.
>
> Patti loves Jason.

However, Russell's idea that the propositional contribution of the verb binds the constituents together (in different ways in the case of our pair of sentences) is hard to understand. In the next to last quotation from Russell above, he suggests that the proposition expressed by '*A* differs from *B*', whose constituents are *A*, difference and *B*, is held together by *difference* actually obtaining between *A* and *B*. If we call *difference* a relation, the proposition would consist of *A* standing in the relation of difference to *B*. Russell makes a number of remarks that suggest that this is his view. But it would seem that this cannot be correct. Intuitively, *A* standing in the relation of difference to *B* is what makes the proposition that *A* differs from *B true*. It is not the proposition itself. For if it were, it would seem that if *A* doesn't stand in the difference relation to *B*, then there is no (false) proposition to the effect that *A* differs from *B*. And quite generally, for the same reason it would appear that there are no false propositions. Perhaps Russell meant that propositional contributions of verbs hold propositional constituents together in some other manner. But it certainly is not clear what that manner would be. Or perhaps he held a view simlar to Zalta's discussed above.

Notes to Structured Propositions

Notes

1. Of course there are always dissenters. For example, Mark Richard [1982] argues that modal operators operate on sentence meanings (functions from contexts and times to propositions). Thus it would seem that it is sentence meanings that have modal properties for Richard. Further, there is some controversy as to whether propositions are the things that possess "tense properties" (e.g. having been true, etc.) and are the things tense operators operate on. Kaplan [1977] thinks so. Richard [1982] and Salmon [1989b] think not.

2. Strictly, Crimmins seems only to claim that sentences sometimes express propositions (in a context), where the propositions expressed contain constituents that are not supplied by any *overt* expression in the sentences. This does not rule out the possibility that such constituents are contributed by covert (phonologically and inscriptionally unrealized) expressions in the sentence. But there are those who have argued that sentences sometimes express propositions that have as constituents elements that are not supplied by any covert *or* overt expressions in the sentence. See Stanley [2000] for discussion.

3. See, for example, Montague [1960] for a discussion of an approach of this general sort.

4. Such a view is suggested in Montague [1960].

5. The interested reader should also consult Richard [1990] and Crimmins [1992] for approaches in the broadly neo-Russellian (as I use the term) tradition that try to avoid various consequences of the Salmon-Soames approach.

6. Peter Hanks presses this point against those who hold that propositions are n-tuples in an unpublished manuscript.

7. It may strike some as odd that I include the views of Cresswell [1985] in an article on structured *propositions* since he explicitly argues against what he calls "the propositional account of belief". But in so doing, he makes assumptions about propositions that modern structured proposition theorists (e.g. neo-Russellians) would reject, such as that ‘5+7=12’ and ‘12=12’ express the same proposition. And Cresswell's own views have much in common with the views of other (non-structured meaning) structured proposition theorists.

8. Actually, Cresswell eventually settles on sets of world/time pairs as sentence intensions; but I ignore

this complication here.

9. I write here as though ‘that’ for Cresswell has only two meanings: on one, it combines with a sentence to form a name of an intension/set of worlds. On the other, it combines with a sentence to form the name of the "maximally fine grained entity" that can be named by a ‘that’ clause containing the sentence. But in fact, (given sentences of sufficient complexity), there are "intermediate" meanings of ‘that’ that combine with the sentence in question to form names of entities whose grain is "between" intension/sets of worlds and the "maximally fine grained entity". This is why I say above that ‘that’ is *highly* ambiguous on Cresswell's view. Again, since our concern here is with more fine grained entities, I ignore this complication and focus on the maximally fine grained entity that can be named by a ‘that’ clause containing a sentence on Cresswell's view.

10. One can easily use this function to define the intension f of ‘runs’ (function from worlds to extensions) as follows: f is the function from worlds to sets of individuals such that o is in f(w) iff w is in I_r(o), where I_r is Cresswell's "intension" (function from individuals to sets of worlds) for ‘runs’.

11. It would seem that Cresswell needs to say this. For recall that sentences don't express fine grained entities in isolation; it is only when combined with ‘that’ (on certain of its meanings) that a fine grained entity is associated with a sentence-plus-'that’. So it appears that the sentence in isolation (without ‘that’ appended) cannot be true or false in virtue of its association with a fine grained that is in the first instance true of false. For in isolation it is not so associated!

12. The use of variables in expressions like ‘Rxy’ here is perhaps unfortunate. I remind the reader that R is a relation (not a predicate). I put variables in to indicate the "argument places" in the relation. Perhaps underlining (___) and other notation to the same effect (#####) would be better. I urge the reader to mentally substitute such things for variables that indicate argument places in relations.

13. For details about the rest of the functions mentioned, consult Zalta [1988], (especially pages 46-51; 58-61, and the Appendix containing his formal intensional logic).

14. For simplicity, I suppress the modal and tense operators that should appear in the instances of the comprehension schema.

Singular Propositions

Singular propositions (also called ‘Russellian propositions’) are propositions that are about a particular object or individual in virtue of having the object or individual as a *constituent* of the proposition. Alleged examples of singular propositions are the propositions that Mont Blanc is more than 4,000 meters high, that Socrates was wise, and that she [pointing to someone] lives in New York. Singular propositions are to be contrasted with *general* propositions and (what we can call) particularized propositions. The former are propositions that are not about any particular item (as opposed to a class or kind of item) and the latter are propositions that are about particulars or individuals but do not contain those individuals as constituents. Examples of the former are the propositions that most Americans favor a tax cut and that some music is great; examples of the latter are the propositions that the inventor of bifocals was bald and that the tallest spy is a man. The acceptance or rejection of singular propositions lies at the center of many issues in semantics, the philosophy of language, and metaphysics.

Sense and Reference

There are, roughly speaking, two kinds of theories in the philosophy of language and many versions of these theories. There are the Fregean theories that employ some version of Frege's distinction between sense and reference and the Russellian theories that employ some version of Russell's theory of scope and incomplete symbols. (One can, of course, combine the two views in various ways but generally such combinations tend to side with Frege over Russell on the nature of propositions and hence count as Fregean in the present context.) Again roughly speaking, Frege distinguished between the referent of an expression or term and the sense of that expression or term. For example, the referent of the term ‘human’ is the set of humans while the sense of the term might be described as the property of being

homo sapiens (although, strictly speaking, senses are not properties). For complex expressions, such as the inventor of bifocals, the sense of the whole expression is a function of the sense of its parts and the referent of the whole expression is a function of the referent of the parts. This is also true for complete sentences. The proposition that is expressed by a sentence is the sense of the sentence which in turn is a function of the senses of the parts of the sense. Thus for Frege objects are *not* constituents of propositions. Propositions are composed of the senses of terms and expressions that refer to objects, but not the objects themselves.

Russell, on the other hand, rejected senses and attempted to solve the problems that senses were introduced to solve by logical analysis and scope distinctions. The result was that propositions expressed by sentences such as "The inventor of bifocals was bald" did not have senses as constituents. However, they did not have objects as constituents either. Roughly speaking, Russell had propositional functions-- functions from objects to propositions-- in place of senses. Yet at the bottom level such a view seems to require singular propositions. These are the basic or atomic propositions upon which the complex propositions are built. Frege's atomic propositions are composed of senses while Russell's require individuals.

Recently, David Kaplan has argued that essential difference between Frege's and Russell's theories of language is nothing more nor less than the acceptance of singular propositions. If we were to add singular propositions to Frege's theory then with some modifications we could reduce Frege's view to Russell's view. Hence, if Kaplan is correct and there are singular propositions as well, then we need not introduce the complexities of a Fregean theory of sense and we can focus our semantical attention on the simpler Russellian theories.

Reasons for Singular Propositions

The primary reasons offered in favor of accepting singular propositions are semantical or linguistic in nature. (Although David Lewis argues that if we accept that there are individuals and properties and pairs of things we accept, then we must accept that there are singular propositions.) Perhaps the strongest of the semantical reasons for singular propositions are those associated with the development of an adequate theory of demonstratives or indexicals. David Kaplan, for example, has argued that indexical expressions (e.g., ‘I’, ‘now’) are what he calls ‘directly referential’ expressions. An expression is *directly referential* if the expression (relative to a context of use) directly refers to its object and the referent is *not* determined or fixed in virtue of the fact that the object in question is characterized by a descriptive property or a Fregean sense.

Let us assume without argument that there are propositions. We make this assumption knowing that many philosophers have serious doubts about the existence of propositions. However, our current purpose is to ask whether there are any positive reasons that can be given in favor of *singular* propositions even granting that there are propositions. We will use an argument that was originally presented by David Kaplan to show that demonstratives are directly referential expressions (and hence are used to express singular propositions). Suppose David is standing at a table with two men; Charles on

his left and Paul on his right. Paul lives in New Jersey and Charles lives in Illinois. David points to the person on his right and says (at time *t*)

(1) He lives in New Jersey.

David has expressed a proposition that we can label *p* that is about Paul. Is *p* a singular proposition; that is, is it a proposition that has Paul as a constituent? Let us begin by assuming that *p*is *not* a singular proposition. If it is not a singular proposition then it does not have Paul as a constituent, but is about Paul is another way. (If *p* is a singular proposition then it is about Paul by having Paul as a constituent.) Consider then the proposition expressed by

(2) The person on David's right (at *t*) lives in New Jersey ,

which we can label *p**. *p** is a proposition about Paul but it does not have Paul as a constituent. Perhaps *p** (or something similar to *p**) is *p*. However, consider a counterfactual circumstance where David had been tricked into thinking that Paul is to his right and that Charles is to his left. That is, suppose, contrary to the facts, Paul and Charles switched places. In such a case *p** would not be true, but *p* would be true. *p** would not be true because the person on David's right, namely Charles, does not live in New Jersey. *p* on the other hand is still true, for though in the counterfactual circumstance Paul and Charles have switched locations relative to David they still live in their respective states in the counterfactual circumstance.

It is important here to be clear about what we are supposing. We are asking what the truth value of the propositions *p* and *p** *would be* in the described counterfactual circumstance. We are *not* asking what proposition would David express by uttering (1) in the counterfactual circumstance. It is true that the proposition expressed by (1) will differ in different circumstances of utterance or different *contexts*. Paul can utter (1) pointing to Charles or Charles can utter (1) pointing to David. In these different contexts different propositions will be expressed.

Nonetheless since *p* and *p** differ in truth value in the described counterfactual circumstance, *p** cannot be *p*. (It is an axiom of propositional theory that if *p* = *p** then *p* and *p** have the same truth value in all counterfactual circumstances.) A similar argument can be presented for any proposition that is in fact about Paul, but could be about someone else in a different counterfactual circumstance. So, for example, if we replaced (2) with

(3) The person David is pointing to lives in New Jersey,

we will run into the same problem.

One might suppose that one can avoid singular propositions by claiming, along lines similar to what David Lewis has argued, that it is a mistake to place any philosophical importance on the question of what is true in a counterfactual circumstance *simplicter*. Counterfactual circumstances are merely one

parameter among many that are necessary to determine truth. What we should say is that (1) is true relative to a complex or structure that contains a *context* and a *counterfactual (or factual) circumstance* among other parameters. Viewed in this light it appears that (1) and (3) have the same truth value given the same parameters. One result with this way of looking at things is that either propositions are identified with sentences (types) or sets of items containing all the necessary parameters (such as sets of possible worlds). David Lewis accepts the latter and in so doing accepts that there are singular propositions. So Lewis's way of looking at things does not avoid commitment to singular propositions. If one accepts that propositions are sentences then one must give up the view that they can be about particulars. For on such a view the proposition David expresses when he says

(4) I am bored.

is the same proposition that Paul, Charles, or anyone else would express were they to utter (4). So it would be a mistake to say that (4) as uttered by David is about David. But then *p* would not be about Paul as we assumed. There are, of course, other reasons to deny that sentences are propositions that properly belong to a general discussion of propositions. Besides it is not completely clear that there is no philosophical significance in dividing things up the way Kaplan does. After all, there is something rather plausible in Kaplan's suggestion that context is used to help determine which proposition is expressed as opposed to being part of a complex that determines the truth of an already present proposition.

Still, given what we have said thus far, it is possible that Paul is not a constituent of *p* but the singleton set of Paul or the property of being Paul is a constituent of *p*. The reason in favor of Paul over his singleton as a constituent of *p* concerns issues of reference in the philosophy of language. Can we *directly* refer to an individual or property? Can we directly refer to the singleton of Paul? If the answer is yes, then we could run into a problem if we claimed that *p* has Paul's singleton as a constituent. Let a be an expression that directly refers to Paul's singleton. Sets, of course, do not live in states so the proposition expressed by the following is false

(5) a lives in New Jersey.

Yet, the proposition expressed by (5) appears to have the same constituents as *p* if Paul's singleton, as opposed to Paul, is a constituent of *p*. This argument is not conclusive since it depends on the assumption that one can refer directly to an item with the use of some linguistic expression and not via some representative of the item. In the end it may not matter whether Paul or some representative of Paul is a constituent of *p* provided that the representative is an essential representative of Paul (i.e., something that represents Paul in all (and only) counterfactual circumstances where Paul can represent himself).

A Modal Argument against Singular Propositions

Although there are some reasons for thinking that there are singular propositions there are also reasons for thinking that there are no singular propositions. Alvin Plantinga, for example, has raised the

following objection. Consider the proposition:

> (6) *Socrates did not exist.*

While (6) is false, it might have been true (here the number designates the proposition (if there is one) as opposed to the sentence). That is, it is possibly true. If (6) had been true, then (6) would have existed. After all, (6) cannot have the property of being true without existing, so had (6) been true then Socrates would not have existed, but (6) would have existed. But if Socrates is a constituent of (6), then (6) cannot exist without Socrates's existing. Therefore, Socrates is not a constituent of (6).

Basically, Plantinga argues that ordinary objects such as persons cannot be constituents of propositions because the propositions can exist without the individual's existing. There are different replies to Plantinga's argument one can make depending on the metaphysical position one takes with respect to modality. If one is a possibilist then one makes a distinction between something's being actual and something's existing (or subsisting or having being of some sort). So Socrates can be a constituent of a proposition even in circumstances where Socrates is not an actual object. On the other hand, if one is an actualist (and accepts singular propositions) then one must deny Plantinga's claim that (6) can exist without Socrates's existing. Here one must argue that (6)'s being possibly true does not imply that (6) can be true without Socrates's existing. As an analogy consider John's assertion "It is possible I do not exist." John can describe or represent a circumstance or world where John does not exist. So, too, (6) can represent a circumstance or world where (6) does not exist. For (6) to be possibly true is for (6) to represent a circumstance or world that could obtain. It is not required that (6) be a part of the world or circumstance that (6) represents any more than it is required that John be a part of the world that he describes with his assertions.

Temporal Problems for Singular Propositions

Another objection that one can raise with respect to singular propositions concerns a fundamental problem of combining so-called abstract objects (such as propositions) with ordinary individuals. Ordinary individuals change over time including coming into and going out of existence. Propositions, on the other hand, are usually taken to be eternal objects--things that do not change over time. Consider then the following proposition:

> (7) *Socrates exists.*

Does (7) exist? Socrates is long gone; he no longer exists. But if (7) does not exist how can it be false? Moreover, if (7) does exist then exactly what age is the constituent of (7)? 21? 37? It seems a bit absurd to say that the age of a constituent of a proposition is thus and so, yet if Socrates himself is a constituent of (7), then he must be a certain age. No human person exists without being a certain age.

Again the reply that one makes to the temporal modal objection is like the reply that one makes to the

alethic modal objection in that it depends on one's metaphysical views concerning time and individuals. If, for example, one accepts the 4D view of objects then as far as age (and other issues involving change of existing objects) goes there is no problem. The object that is a constituent of a proposition is a complete object in that all the temporal stages or parts of the object in question are involved. So part of Socrates is 21 and part is 37.

On the other hand, if one holds to a 3D view where the object is wholly present at each time that it exists, then matters become a bit more complex. There are different ways to go. For example, one could hold that at each time, *t*, at which Socrates existed there is a singular proposition involving Socrates and *t* (and perhaps the property of existence if it is a property). On one such view there is no such proposition as (7). So the question of the age (and other features of changing existing objects) will depend on the time involved in the proposition under consideration. On another view (7) expresses the conjunction of all such propositions, hence the question of age does not arise.

When we ask (on either view) how can an object that no longer exists be a constituent of a proposition, we need to consider the various metaphysical views concerning ordinary individuals. If we can think of (or refer to) Socrates even though Socrates does not exist, then Socrates can be a constituent of a proposition though Socrates does not exist. What then shall we say of the proposition that Socrates exists? Does it exist or not? If it does not exist, then that does not prevent us from thinking of it (as with Socrates). On the other hand if we are prevented from thinking of Socrates because he no longer exists, then there are no singular propositions about Socrates. But that does not prevent there from being singular propositions about currently existing objects. One must simply give up the view that propositions are eternal.

The question of whether there are singular propositions, like the general question of whether there are propositions at all, has not been settled. Different philosophers take different positions on this issue. However, there remains a major advantage for accepting some form of singular propositions, namely, on such a view is clear how propositions represent or describe the world.

Set Theory

Set Theory is the mathematical science of the infinite. It studies properties of sets, abstract objects that pervade the whole of modern mathematics. The language of set theory, in its simplicity, is sufficiently universal to formalize all mathematical concepts and thus set theory, along with Predicate Calculus, constitutes the true Foundations of Mathematics. As a mathematical theory, Set Theory possesses a rich internal structure, and its methods serve as a powerful tool for applications in many other fields of Mathematics. Set Theory, with its emphasis on consistency and independence proofs, provides a gauge for measuring the consistency strength of various mathematical statements. There are four main directions of current research in set theory, all intertwined and all aiming at the ultimate goal of the theory: to describe the structure of the mathematical universe. They are: inner models, independence proofs, large cardinals, and descriptive set theory. See the relevant sections in what follows.

---

1. The Essence of Set Theory

The objects of study of Set Theory are *sets*. As sets are fundamental objects that can be used to define all other concepts in mathematics, they are not defined in terms of more fundamental concepts. Rather, sets are introduced either informally, and are understood as something self-evident, or, as is now standard in modern mathematics, axiomatically, and their properties are postulated by the appropriate formal axioms.

The language of set theory is based on a single fundamental relation, called *membership*. We say that A is a member of B (in symbols $A \in B$), or that the set B contains A as its element. The understanding is that a set is determined by its elements; in other words, two sets are deemed equal if they have exactly the same elements. In practice, one considers sets of numbers, sets of points, sets of functions, sets of some other sets and so on. In theory, it is not necessary to distinguish between objects that are members and objects that contain members -- the only objects one needs for the theory are sets. See the supplement

Basic Set Theory

for further discussion.

Using the membership relation one can derive other concepts usually associated with sets, such as unions and intersections of sets. For example, a set C is the union of two sets A and B if its members are exactly those objects that are either members of A or members of B. The set C is uniquely determined, because we have specified what its elements are. There are more complicated operations on sets that can be defined in the language of set theory (i.e. using only the relation $\in$), and we shall not concern ourselves with those. Let us mention another operation: the (unordered) *pair* $\{A,B\}$ has as its elements exactly the sets $A$and B. (If it happens that $A=B$, then the "pair" has exactly one member, and is called a *singleton* $\{A\}$.) By combining the operations of union and pairing, one can produce from any finite list of sets the set that contains these sets as members: $\{A,B,C,D,...,K,L,M\}$. We also mention the *empty set*, the set that has no elements. (The empty set is uniquely determined by this property, as it is the only set that has no elements - this is a consequence of the understanding that sets are determined by their elements.)

When dealing with sets informally, such operations on sets are self-evident; with the axiomatic approach, it is postulated that such operations can be applied: for instance, one postulates that for any sets A and B, the set $\{A,B\}$ exists. In order to endow set theory with sufficient expressive power one needs to postulate more general construction principles than those alluded to above. The guiding principle is that any objects that can be singled out by means of the language can be collected into a set. For instance, it is desirable to have the "set of all integers that are divisible by number 3," the "set of all straight lines in the Euclidean plane that are parallel to a given line", the "set of all continuous real functions of two real variables" etc. Thus one is tempted to postulate that given any property P, there exists a set whose members are exactly all the sets that have property P. As we shall see below, such an assumption is logically inconsistent, and the accepted construction principles are somewhat weaker than such a postulate.

One of the basic principles of set theory is the existence of an infinite set. The concept can be formulated precisely in the language of set theory, using only the membership relation, and the definition captures the accepted meaning of "infinite". See the supplement on

Basic Set Theory

for further discussion. Using the basic construction principles, and assuming the existence of infinite sets, one can *define* numbers, including integers, real numbers and complex numbers, as well as functions, functionals, geometric and topological concepts, and all objects studied in mathematics. In this sense, set theory serves as *Foundations of Mathematics*. The significance of this is that all questions of provability (or unprovability) of mathematical statements can be in principle reduced to formal questions of formal derivability from the generally accepted axioms of Set Theory.

While the fact that all of mathematics can be reduced to a formal system of set theory is significant, it would hardly be a justification for the study of set theory. It is the internal structure of the theory that makes it worthwhile, and it turns out that this internal structure is enormously complex and interesting. Moreover, the study of this structure leads to significant questions about the nature of the mathematical universe.

The fundamental concept in the theory of infinite sets is the *cardinality* of a set. Two sets *A* and *B* have the *same cardinality* if there exists a mapping from the set *A* onto the set *B* which is *one-to-one*, that is, it assigns each element of *A* exactly one element of *B*. It is clear that when two sets are finite, then they have the same cardinality if and only if they have the same number of elements. One can extend the concept of the "number of elements" to arbitrary, even infinite, sets. It is not apparent at first that there might be infinite sets of different cardinalities, but once this becomes clear, it follows quickly that the structure so described is rich indeed.

2. Origins of Set Theory

The birth of Set Theory dates to 1873 when Georg Cantor proved the uncountability of the real line. (One could even argue that the exact birthdate is December 7, 1873, the date of Cantor's letter to Dedekind informing him of his discovery.) Until then, no one envisioned the possibility that infinities come in different sizes, and moreover, mathematicians had no use for "actual infinity." The arguments using infinity, including the Differential Calculus of Newton and Leibniz, do not require the use of infinite sets, and infinity appears only as "a manner of speaking", to paraphrase Friedrich Gauss. The fact that the set of all positive integers has a proper subset, like the set of squares {1, 4, 9, 16, 25,...} of the same cardinality (using modern terminology) was considered somewhat paradoxical (this had been discussed at length by Galileo among others). Such apparent paradoxes prevented Bernhard Bolzano in 1840s from developing set theory, even though some of his ideas are precursors of Cantor's work. (It should be mentioned that Bolzano, an accomplished mathematician himself, coined the word *Menge* (= set) that Cantor used for objects of his theory.)

Motivation for Cantor's discovery of Set Theory came from his work on Fourier series (which led him to introduce *ordinal numbers*) and on trancendental numbers. Real numbers that are solutions of polynomial equations with integer coefficients are called algebraic, and the search was on for numbers that are not algebraic. A handful of these, called transcendental numbers, was discovered around that time, and a question arose how rare such numbers are. What Cantor did was to settle this question in an unexpected way, showing in one fell swoop that transcendental numbers are plentiful indeed. His famous proof went

as follows: Let us call an infinite set *A countable*, if its elements can be enumerated; in other words, arranged in a sequence indexed by positive integers: $a(1)$, $a(2)$, $a(3)$, … , $a(n)$, … . Cantor observed that many infinite sets of numbers are countable: the set of all integers, the set of all rational numbers, and also the set of all algebraic numbers. Then he gave his ingeneous diagonal argument that proves, by contradiction, that the set of all real numbers is *not* countable. A consequence of this is that there exists a multitude of transcendental numbers, even though the proof, by contradiction, does not produce a single specific example. See the supplement on

Basic Set Theory

for further discussion.

Cantor's discovery of uncountable sets led him to the subsequent development of ordinal and cardinal numbers, with their underlying order and arithmetic, as well as to a plethora of fundamental questions that begged to be answered (such as the Continuum Hypothesis). After Cantor, mathematics has never been the same.

3. The Continuum Hypothesis

As the Continuum Hypothesis has been the most famous problem in Set Theory, let me explain what it says. The smallest infinite cardinal is the cardinality of a countable set. The set of all integers is countable, and so is the set of all rational numbers. On the other hand, the set of all real numbers is uncountable, and its cardinal is greater than the least infinite cardinal. A natural question arises: is this cardinal (*the continuum*) the very next cardinal. In other words, is it the case that there are no cardinals between the countable and the continuum? As Cantor was unable to find any set of real numbers whose cardinal lies strictly between the countable and the continuum, he conjectured that the continuum is the next cardinal: the Continuum Hypothesis. Cantor himself spent most of the rest of his life trying to prove the Continuum Hypothesis and many other mathematicians have tried too. One of these was David Hilbert, the leading mathematician of the last decades of the 19th century. At the World Congress of Mathematicians in Paris in 1900 Hilbert presented a list of major unsolved problems of the time, and the Continuum Hypothesis was the very first problem on Hilbert's list.

Despite the effort of a number of mathematicians, the problem remained unsolved until 1963, and it can be argued that in some sense the problem is still unsolved. See Section 7 on Independence Proofs.

4. Axiomatic Set Theory

In the years following Cantor's discoveries, development of Set Theory proceeded with no particular concern about how exactly sets should be defined. Cantor's informal "definition" was sufficient for proofs in the new theory, and the understanding was that the theory can be formalized by rephrasing the

informal definition as a *system of axioms*. In the early 1900s it became clear that one has to state precisely what basic assumptions are made in Set Theory; in other words, the need has arisen to axiomatize Set Theory. This was done by Ernst Zermelo, and the immediate reasons for his axioms were twofold. The first one was the discovery of a paradox in Set Theory. This paradox is referred to as *Russell's Paradox.* Consider the "set" S of all sets that are not an element of itself. If one accepts the principle that all such sets can be collected into a set, then S should be a set. It is easy to see however that this leads to a contradiction (is the set S an element of itself?)

Russell's Paradox can be avoided by a careful choice of construction principles, so that one has the expressive power needed for usual mathematical arguments while preventing the existence of paradoxical sets. See the supplement on

Zermelo-Fraenkel Set Theory

for further discussion. The price one has to pay for avoiding inconsistency is that some "sets" do not exist. For instance, there exists no "universal" set (the set of all sets), no set of all cardinal numbers, etc.

The other reason for axioms was more subtle. In the course of development of Cantor's theory of cardinal and ordinal numbers a question was raised whether every set can be provided with a certain structure, called *well-ordering* of the set. Zermelo proved that indeed every set can be well-ordered, but only after he introduced a new axiom that did not seem to follow from the other, more self-evident, principles. His *Axiom of Choice* has become a standard tool of modern mathematics, but not without numerous objections of some mathematicians and discussions in both mathematical and philosophical literature. The history of the Axiom of Choice bears strong resemblance to that of the other notorious axiom, Euclid's Fifth Postulate.

5. The Axiom of Choice

The Axiom of Choice states that for every set of mutually disjoint nonempty sets there exists a set that has exactly one member common with each of these sets. For instance, let S be a set whose members are mutually disjoint finite sets of real numbers. We can *choose* in each $X \in S$ the smallest number, and thus form a set that has exactly one member in common with each $X \in S$. What is not self-evident is whether we can make a choice every time, simultaneously for infinitely many sets X, regardless what these abstract sets are. The Axiom of Choice, which postulates the existence of a certain set (*the choice set*) without giving specific instructions how to construct such a set, is of different nature than the other axioms, which all formulate certain construction principles for sets. It was this nonconstructive nature of the Axiom of Choice that fed the controversy for years to come.

An interesting application of the Axiom of Choice is the Banach-Tarski Paradox that states that the unit ball can be partitioned into a finite number of disjoint sets which then can be rearranged to form *two* unit balls. This is of course a paradox only when we insist on visualizing abstract sets as something that exists

in the physical world. The sets used in the Banach-Tarski Paradox are not physical objects, even though they do exist in the sense that their existence is proved from the axioms of mathematics (including the Axiom of Choice).

The legitimate question is whether the Axiom of Choice is consistent, that is whether it cannot be refuted from the other axioms. (Notice the similarity with the non Euclidean geometry.) This question was answered by Gödel, and eventually the role of the Axiom of Choice has been completely clarified. See Section 7 on Independence Proofs.

6. Inner Models

In the 1930s, Gödel stunned the mathematical world by discovering that mathematics is incomplete. His Incompleteness Theorem states that every axiomatic system that purports to describe mathematics as we know it must be incomplete, in the sense that one can find a true statement expressible in the system that cannot be formally proved from the axioms. In view of this result one must consider the possibility that a mathematical conjecture that resists a proof might be an example of such an unprovable statement, and Gödel immediately embarked on the project of showing that the Continuum Hypothesis might be undecidable in the axiomatic set theory.

Several years after proving the Incompleteness Theorem, Gödel proved another groundbreaking result: he showed that both the Axiom of Choice and the Continuum Hypothesis are consistent with the axioms of set theory, that is that neither can be refuted by using those axioms. This he achieved by discovering a model of set theory in which both the Axiom of Choice and the Continuum Hypothesis are true.

Gödel’s model *L* of “constructible sets” has since served as a blueprint for building so-called *inner models*. These models form a hierarchy, corresponding to the hierarchy of large cardinals (see Section 8), and provide a glimpse into the as yet hidden structure of the mathematical universe. The advances in Inner Model Theory that have been made in the recent past owe much to the work of Ronald Jensen who introduced the study of the fine structure of constructible sets.

7. Independence Proofs

In 1963, Paul Cohen proved independence of the Axiom of Choice and of the Continuum Hypothesis. This he did by applying the *method of forcing* that he invented and constructing first a model of set theory (with the axiom of choice) in which the Continuum Hypothesis fails, and then a model of set theory in which the Axiom of Choice fails. Together with Gödel’s models, these models show that the Axiom of Choice can neither be proved nor refuted from the other axioms, and that the Continuum Hypothesis can neither be proved nor refuted from the axioms of set theory (including the Axiom of Choice).

Cohen's method proved extremely fruitful and led first to the solution of a number of outstanding problems (Suslin's Problem, the Lebesgue measurability Problem, Borel's Conjecture, Kaplansky's Conjecture, Whitehead's Problem and so on) and soon has become one of the cornerstones of modern set theory. The technique of forcing has to date been applied by hundreds of authors of numerous articles and has enormously advanced our knowledge of Foundations of Mathematics. Along with the theory of large cardinals it is used to gauge the consistency strength of mathematical statements.

8. Large Cardinals

In 1930, while working on the Measure Problem, Stanislaw Ulam discovered an important phenomenon: Assuming that a certain mathematical statement about "small sets" (such as sets of real numbers) is true, one can prove the existence of sets of enormous size (*inaccessible*). This phenomenon has become more apparent after Dana Scott's celebrated result (1961) that mesurable cardinals do not exist in *L*. Suddenly, large cardinals such as inaccessible, measurable, supercompact etc. have become the main focus of attention of set theorists. What emerged is a hierarchy of properties of infinite sets, the Large Cardinal Theory, that appears to be the basis for the structure of the set theoretical universe. Large cardinal axioms (also referred to as axioms of *strong infinity*) form a hierarchy whereby a stronger axiom not only implies a weaker axiom but also proves its consistency. To date there are scores of examples of mathematical statements whose consistency strength can be precisely calculated in terms of the hierarchy of large cardinals.(For instance, a negative solution of the Singular Cardinal Problem corresponds to a large cardinal axiom between measurabily and supercompactness.)

Since the pioneering work of Ronald Jensen, Large Cardinal Theory has been closely tied with Inner Model Theory. It turns out that for each large cardinal axiom at lower levels of the hierarchy one can find an appropriate inner model. These inner models shed additional light on the structure of the universe by employing methods of Descriptive Set Theory.

9. Descriptive Set Theory

Descriptive Set Theory traces its origins to the theory of integration by Henri Lebesgue at the beginning of 20th century. Investigations into Borel sets of real numbers led to the theory of *projective* sets, and more generally, the theory of definable sets of real numbers. Following Gödel's work, it became apparent that many natural questions in Descriptive Set Theory are undecidable in axiomatic set theory. This was further confirmed by a proliferation of independence results following Cohen's invention of the forcing method.

Modern Descriptive Set Theory revolves mostly around the powerful method using infinite games. The branch of Descriptive Set Theory known as *Determinateness*, developed by D. A. Martin, Robert Solovay and others, brought together methods of, among others, Recursion Theory and Large Cardinal Theory and has been very successful in describing the structure of definable sets. More importantly, Descriptive Set Theory provides strong evidence for the large cardinal axioms.

Supplement to Set Theory

Basic Set Theory

The following basic facts are excerpted from “Introduction to Set Theory,” Third Edition, by Karel Hrbacek and Thomas Jech, published by Marcel Dekker, Inc., New York 1999.

---

1. Ordered Pairs

We begin by introducing the notion of the *ordered pair*. If a and b are sets, then the *unordered pair* $\{a, b\}$ is a set whose elements are exactly a and b. The “order” in which a and b are put together plays no role; $\{a, b\} = \{b, a\}$. For many applications, we need to pair a and b in a way making possible to “read off” which set comes “first” and which comes “second.” We denote this *ordered pair* of a and b by (a, b); a is the *first coordinate* of the pair (a, b), b is the *second coordinate*.

As any object of our study, the ordered pair has to be a set. It should be defined in such a way that two ordered pairs are equal if and only if their first coordinates are equal and their second coordinates are equal. This guarantees in particular that $(a, b) \neq (b,a)$ if $a \neq b$.

> **Definition.** $(a, b) = \{\{a\}, \{a, b\}\}$.

If $a \neq b$, (a, b) has two elements, a singleton $\{a\}$ and an unordered pair $\{a, b\}$. We find the first coordinate by looking at the element of $\{a\}$. The second coordinate is then the other element of $\{a, b\}$. If $a = b$, then $(a, a) = \{\{a\}, \{a,a\}\} = \{\{a\}\}$ has only one element. In any case, it seems obvious that both coordinates can be uniquely “read off” from the set (a, b). We make this statement precise in the

following theorem.

> **Theorem.** $(a, b) = (a', b')$ if and only if $a = a'$ and $b = b'$.

> *Proof*. If $a = a'$ and $b = b'$, then, of course, $(a, b) = \{\{a\}, \{a, b\}\} = \{\{a'\}, \{a', b'\}\} = (a', b')$. The other implication is more intricate. Let us assume that $\{\{a\}, \{a, b\}\} = \{\{a'\}, \{a', b'\}\}$. If $a \neq b$, $\{a\} = \{a'\}$ and $\{a, b\} = \{a', b'\}$. So, first, $a = a'$ and then $\{a, b\} = \{a, b'\}$ implies $b = b'$. If $a = b$, $\{\{a\}, \{a, a\}\} = \{\{a\}\}$. So $\{a\} = \{a'\}$, $\{a\} = \{a', b'\}$, and we get $a = a' = b'$, so $a = a'$ and $b = b'$ holds in this case, too. □

With ordered pairs at our disposal, we can define *ordered triples*

$$(a, b, c) = ((a, b), c),$$

ordered quadruples

$$(a, b, c, d) = ((a, b, c), d),$$

and so on. Also, we define ordered “*one-tuples*"

$$(a) = a.$$

2. Relations

A binary relation is determined by specifying all ordered pairs of objects in that relation; it does not matter by what property the set of these ordered pairs is described. We are led to the following definition.

> **Definition.** A set R is a *binary relation* if all elements of R are ordered pairs, i.e., if for any $z \in R$ there exist x and y such that $z = (x, y)$.

It is customary to write xRy instead of $(x, y) \in R$. We say that x *is in relation* R *with* y if xRy holds.

The set of all x which are in relation R with some y is called the *domain* of R and denoted by “dom R.” So dom $R = \{x \mid$ there exists y such that $xRy\}$. dom R is the set of all first coordinates of ordered pairs in R.

The set of all y such that, for some x, x is in relation R with y is called the *range* of R, denoted by “ran R.” So ran $R = \{y \mid$ there exists x such that $xRy\}$.

3. Functions

Function, as understood in mathematics, is a procedure, a rule, assigning to any object *a* from the domain of the function a unique object *b*, the value of the function at *a*. A function, therefore, represents a special type of relation, a relation where every object *a* from the domain is related to precisely one object in the range, namely, to the value of the function at *a*.

> **Definition.** A binary relation F is called a *function* (or *mapping*, *correspondence*) if aFb_1 and aFb_2 imply $b_1 = b_2$ for any a, b_1, and b_2. In other words, a binary relation F is a function if and only if for every a from dom F there is exactly one b such that aFb. This unique b is called the *value of F at a* and is denoted $F(a)$ or F_a. [$F(a)$ is not defined if $a \notin$ dom F.] If F is a function with dom $F = A$ and ran $F \subseteq B$, it is customary to use the notations $F : A \mapsto B$, $\langle F(a) \mid a \in A \rangle$, $\langle F_a \mid a \in A \rangle$, $\langle F_a \rangle_{a \in A}$ for the function F. The range of the function F can then be denoted $\{F(a) \mid a \in A\}$ or $\{F_a\}_{a \in A}$.

The Axiom of Extensionality can be applied to functions as follows.

> **Lemma.** Let F and G be functions. $F = G$ if and only if dom F = dom G and $F(x) = G(x)$ for all $x \in$ dom F.

A function f is called *one-to-one* or *injective* if $a_1 \in$ dom f, $a_2 \in$ dom f, and $a_1 \neq a_2$ implies $f(a_1) \neq f(a_2)$. In other words if $a_1 \in$ dom f, $a_2 \in$ dom f, and $f(a_1) = f(a_2)$, then $a_1 = a_2$.

4. Natural Numbers

In order to develop mathematics within the framework of the axiomatic set theory, it is necessary to define natural numbers. We all know natural numbers intuitively: 0, 1, 2, 3, ..., 17, …, 324, etc., and we can easily give examples of sets having zero, one, two, or three elements.

To define number 0, we choose a representative of all sets having no elements. But this is easy, since there is only one such set. We define $0 = \emptyset$. Let us proceed to sets having one element (singletons): $\{\emptyset\}$, $\{\{\emptyset\}\}$, $\{\{\emptyset, \{\emptyset\}\}\}$; in general, $\{x\}$. How should we choose a representative? Since we already defined one particular object, namely 0, a natural choice is $\{0\}$. So we define

$$1 = \{0\} = \{\emptyset\}.$$

Next we consider sets with two elements: $\{\emptyset, \{\emptyset\}\}$, $\{\{\emptyset\}, \{\emptyset, \{\emptyset\}\}\}$, $\{\{\emptyset\}, \{\{\emptyset\}\}\}$, etc. By now, we have defined 0 and 1, and $0 \neq 1$. We single out a particular two-element set, the set whose elements are the previously defined numbers 0 and 1:

$$2 = \{0,1\} = \{\emptyset, \{\emptyset\}\}.$$

It should begin to be obvious how the process continues:

> $3 = \{0, 1, 2\} = \{\emptyset, \{\emptyset\}, \{\emptyset,\{\emptyset\}\}\}$
> $4 = \{0, 1, 2, 3\} = \{\emptyset,\{\emptyset\}, \{\emptyset,\{\emptyset\}\}, \{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}\}\}$
> $5 = \{0, 1, 2, 3, 4\}$etc.

The idea is simply to define a natural number n as the set of all smaller natural numbers: $\{0, 1, \ldots, n - 1\}$. In this way, n is a particular set of n elements.

This idea still has a fundamental deficiency. We have defined 0, 1, 2, 3, 4, and 5 and could easily define 17 and—not so easily—324. But no list of such definitions tells us what a natural number is in general. We need a statement of the form: A set n is a natural number if …. We cannot just say that a set n is a natural number if its elements are all the smaller natural numbers, because such a “definition” would involve the very concept being defined.

Let us observe the construction of the first few numbers again. We defined $2 = \{0, 1\}$. To get 3, we had to adjoin a third element to 2, namely, 2 itself:

> $3 = 2 \cup \{2\} = \{0, 1\} \cup \{2\}$.

Similarly,

> $4 = 3 \cup \{3\} = \{0, 1, 2\} \cup \{3\}$,
> $5 = 4 \cup \{4\}$,etc.

Given a natural number n, we get the “next” number by adjoining one more element to n, namely, n itself. The procedure works even for 1 and 2: $1 = 0 \cup \{0\}$, $2 = 1\cup\{1\}$, but, of course, not for 0, the least natural number.

These considerations suggest the following.

> **Definition.** The *successor* of a set x is the set $S(x) = x \cup \{x\}$.

Intuitively, the successor $S(n)$ of a natural number n is the “one bigger” number $n + 1$. We use the more suggestive notation n+1 for S(n) in what follows. We later define addition of natural numbers (using the notion of successor) in such a way that $n + 1$ indeed equals the sum of n and 1. Until then, it is just a notation, and no properties of addition are assumed or implied by it.

We can now summarize the intuitive understanding of natural numbers as follows:

a. 0 is a natural number.

b. If n is a natural number, then its successor $n + 1$ is also a natural number.
c. All natural numbers are obtained by application of (a) and (b), i.e., by starting with 0 and repeatedly applying the successor operation: 0, 0 + 1 = 1, 1 + 1 = 2, 2 + 1 = 3, 3 + 1 = 4, 4 + 1 = 5, …etc.

Definition. A set I is called *inductive* if

1. $0 \in I$.
2. If $n \in I$, then $(n + 1) \in I$.

An inductive set contains 0 and, with each element, also its successor. According to (c), an inductive set should contain all natural numbers. The precise meaning of (c) is that the set of natural numbers is an inductive set which contains no other elements but natural numbers, i.e., it is the *smallest* inductive set. This leads to the following definition.

Definition. *The set of all natural numbers* is the set

$$\mathbb{N} = \{x \mid x \in I \text{ for every inductive set } I\}.$$

The elements of $\mathbb{N}$ are called *natural numbers*. Thus a set x is a natural number if and only if it belongs to every inductive set.

5. Cardinality of Sets

From the point of view of pure set theory, the most basic question about a set is: How many elements does it have? It is a fundamental observation that we can define the statement “sets A and B have the same number of elements” without knowing anything about numbers.

Definition. Sets A and B have *the same cardinality* if there is a one-to-one function f with domain A and range B. We denote this by $|A| = |B|$.

Definition. The cardinality of A is less than or equal to the cardinality of B (notation: $|A| \leq |B|$) if there is a one-to-one mapping of A into B.

Notice that $|A| \leq |B|$ means that $|A| = |C|$ for some subset C of B. We also write $|A| < |B|$ to mean that $|A| \leq |B|$ and not $|A| = |B|$, i.e., that there is a one-to-one mapping of A onto a subset of B, but there is no one-to-one mapping of A onto B.

Lemma.

1. If $|A| \leq |B|$ and $|A| = |C|$, then $|C| \leq |B|$.

2. If $|A| \preceq |B|$ and $|B| = |C|$, then $|A| \preceq |C|$.
3. $|A| \preceq |A|$.
4. If $|A| \preceq |B|$ and $|B| \preceq |C|$, then $|A| \preceq |C|$.

Cantor-Bernstein Theorem. If $|X| \preceq |Y|$ and $|Y| \preceq |X|$, then $|X| = |Y|$.

6. Finite Sets

Finite sets can be defined as those sets whose size is a natural number.

> **Definition.** A set S is *finite* if it has the same cardinality as some natural number $n \in \mathbb{N}$. We then define $|S| = n$ and say that *S has n elements*. A set is *infinite* if it is not finite.

7. Countable Sets

> **Definition.** A set S is *countable* if $|S| = |\mathbb{N}|$. A set S is *at most countable* if $|S| \preceq |\mathbb{N}|$.

Thus a set S is countable if there is a one-to-one mapping of $\mathbb{N}$ onto S, that is, if S is the range of an infinite one-to-one sequence.

> **Theorem.** An infinite subset of a countable set is countable.
>
> *Proof*. Let A be a countable set, and let $B \subseteq A$ be infinite. There is an infinite one-to-one sequence $\langle a_n \rangle_{n=0}^{\infty}$, whose range is A. We let $b_0 = a_{k_0}$, where k_0 is the least k such that $a_k \in B$. Having constructed b_n, we let $b_{n+1} = a_{k_{n+1}}$, where k_{n+1} is the least k such that $a_k \in B$ and $a_k \neq b_i$ for every $i \leq n$. Such k exists since it is easily seen that $B = \{b_n \mid n \in \mathbb{N}\}$ and that $\langle b_n \rangle_{n=0}^{\infty}$ is one-to-one. Thus B is countable. □
>
> **Corollary.** A set is at most countable if and only if it is either finite or countable.

The range of an infinite one-to-one sequence is countable. If $\langle a_n \rangle_{n=0}^{\infty}$ is an infinite sequence which is not one-to-one, then the set $\{a_n\}_{n=0}^{\infty}$ may be finite (e.g., this happens if it is a constant sequence). However, if the range is infinite, then it is countable.

> **Theorem.** The range of an infinite sequence $\langle a_n \rangle_{n=0}^{\infty}$ is at most countable, i.e., either finite or countable. (In other words, the image of a countable set under any mapping is at most countable.)

Proof. By recursion, we construct a sequence $\langle b_n \rangle$ (with either finite or infinite domain) which is one-to-one and has the same range as $\langle a_n \rangle_{n=0}^{\infty}$. We let $b_0 = a_0$, and, having constructed b_n, we let $b_{n+1} = a_{k_{n+1}}$, where k_{n+1} is the least k such that $a_k \neq b_i$ for all $i \leq n$. (If no such k exists, then we consider the finite sequence $\langle b_i \mid i \leq n \rangle$.) The sequence $\langle b_i \rangle$ thus constructed is one-to-one and its range is $\{a_n\}_{n=0}^{\infty}$. □

One should realize that not all properties of size carry over from finite sets to the infinite case. For instance, a countable set S can be decomposed into two disjoint parts, A and B, such that $|A| = |B| = |S|$; that is inconceivable if S is finite (unless $S = \varnothing$).

Namely, consider the set $E = \{2k \mid k \in \mathbb{N}\}$ of all even numbers, and the set $O = \{2k + 1 \mid k \in \mathbb{N}\}$ of all odd numbers. Both E and O are infinite, hence countable; thus we have $|\mathbb{N}| = |E| = |O|$ while $\mathbb{N} = E \cup O$ and $E \cap O = \varnothing$.

We can do even better. Let p_n denote the n^{th} prime number (i.e., $p_0 = 2$, $p_1 = 3$, etc.). Let

$$S_0 = \{2^k \mid k \in \mathbb{N}\}, S_1 = \{3^k \mid k \in \mathbb{N}\}, \ldots, S_n = \{p_n^k \mid k \in \mathbb{N}\}, \ldots.$$

The sets S_n ($n \in \mathbb{N}$) are mutually disjoint countable subsets of $\mathbb{N}$. Thus we have $\mathbb{N} \supseteq \bigcup_{n=0}^{\infty} S_n$, where $|S_n| = |\mathbb{N}|$ and the S_ns are mutually disjoint.

The following two theorems show that simple operations applied to countable sets yield countable sets.

Theorem. The union of two countable sets is a countable set.

Proof. Let $A = \{a_n \mid n \in \mathbb{N}\}$ and $B = \{b_n \mid n \in \mathbb{N}\}$ be countable. We construct a sequence $\langle c_n \rangle_{n=0}^{\infty}$ as follows:

$$c_{2k} = a_k \text{and } c_{2k+1} = b_k \text{ for all } k \in \mathbb{N}.$$

Then $A \cup B = \{c_n \mid n \in \mathbb{N}\}$ and since it is infinite, it is countable. □

Corollary. The union of a finite system of countable sets is countable.

Proof. By induction (on the size of the system). □

Theorem. If A and B are countable, then $A \times B$ is countable.

Proof. It suffices to show that $|\mathbb{N} \times \mathbb{N}| = |\mathbb{N}|$, i.e., to construct either a one-to-one mapping of $\mathbb{N} \times \mathbb{N}$ onto $\mathbb{N}$ or a one-to-one sequence with range $\mathbb{N} \times \mathbb{N}$. Consider the function

$$f(k, n) = 2^k \cdot (2n + 1) - 1.$$

It is easy to verify that f is one-to-one and that the range of f is $\mathbb{N}$. □

Corollary. The cartesian product of a finite number of countable sets is countable. Consequently, $\mathbb{N}^m$ is countable, for every $m > 0$.

Theorem. Let $\langle A_n \mid n \in \mathbb{N}\rangle$ be a countable system of at most countable sets, and let $\langle a_n \mid n \in \mathbb{N}\rangle$ be a system of enumerations of A_n; i.e., for each $n \in \mathbb{N}$, $a_n = \langle a_n(k) \mid k \in \mathbb{N}\rangle$ is an infinite sequence, and $A_n = \{a_n(k) \mid k \in \mathbb{N}\}$. Then $\bigcup_{n=0}^{\infty} A_n$ is at most countable.

Proof. Define $f : \mathbb{N} \times \mathbb{N} \mapsto \bigcup_{n=0}^{\infty} A_n$ by $f(n, k) = a_n(k)$. f maps $\mathbb{N} \times \mathbb{N}$ onto $\bigcup_{n=0}^{\infty} A_n$, so the latter is at most countable. □

As a corollary of this result we can now prove

Theorem. If A is countable, then the set Seq (A) of all finite sequences of elements of A is countable.

Proof. It is enough to prove the theorem for $A = \mathbb{N}$. As Seq ($\mathbb{N}$) = $\bigcup_{n=0}^{\infty} \mathbb{N}^n$, the theorem follows if we can produce a sequence $\langle a_n \mid n \geq 1\rangle$ of enumerations of $\mathbb{N}^n$. We do that by recursion.

Let g be a one-to-one mapping of $\mathbb{N}$ onto $\mathbb{N} \times \mathbb{N}$. Define recursively

$a_1(i) = \langle i\rangle$ for all $i \in \mathbb{N}$;
$a_{n+1}(i) = \langle b_0, \ldots, b_{n-1}, i_2\rangle$ where $g(i)=(i_1, i_2)$ and $\langle b_0, \ldots, b_{n-1}\rangle = a_n(i_1)$,for all $i \in \mathbb{N}$.

The idea is to let $a_{n+1}(i)$ be the $(n + 1)$-tuple resulting from the concatenation of the $(i_1)^{\text{th}}$ n-tuple (in the previously constructed enumeration of n-tuples, a_n) with i_2. An easy proof by induction shows that a_n is onto $\mathbb{N}^n$, for all $n \geq 1$, and therefore $\bigcup_{n=1}^{\infty} \mathbb{N}^n$ is countable.

Since $\mathbb{N}^0 = \{<>\}$, $\bigcup_{n=0}^{\infty} \mathbb{N}^n$ is also countable. □

Corollary. The set of all finite subsets of a countable set is countable.

Proof. The function F defined by $F(<a_0, \ldots, a_{n-1}>) = \{a_0, \ldots, a_{n-1}\}$ maps the countable set Seq (A) onto the set of all finite subsets of A. □

Other useful results about countable sets are the following.

Theorem. The set of all integers **Z** and the set of all rational numbers **Q** are countable.

Proof. **Z** is countable because it is the union of two countable sets:

$$\mathbf{Z} = \{0, 1, 2, 3, \ldots\} \cup \{-1, -2, -3, \ldots\}.$$

Q is countable because the function $f : \mathbf{Z} \times (\mathbf{Z} - \{0\}) \mapsto \mathbf{Q}$ defined by $f(p, q) = p / q$ maps a countable set onto **Q**. □

8. Real Numbers

Definition. An ordered set $(X, <)$ is *dense* if it has at least two elements and if for all $a, b \in X$, $a < b$ implies that there exists $x \in X$ such that $a < x < b$.

Let us call the least and the greatest elements of a linearly ordered set (if they exist) the *endpoints* of the set.

The most important example of a countable dense linearly ordered set is the set **Q** of all rational numbers, ordered by size. The ordering is dense because, if r, s are rational numbers and $r < s$, then $x = (r + s) / 2$ is also a rational number, and $r < x < s$. Moreover, (**Q**,<) has no endpoints (if $r \in \mathbf{Q}$ then $r + 1$, $r - 1 \in \mathbf{Q}$ and $r - 1 < r < r + 1$).

Definition. Let $(P, <)$ be a dense linearly ordered set. P is *complete* if every non-empty $S \subseteq P$ bounded from above has a supremum.

The ordered set (**Q**, <) of rationals has a unique completion (up to isomorphism); this is the ordered set of real numbers. The completion of (**Q**, <) is denoted $(\mathbb{R}, <)$; the elements of $\mathbb{R}$ are the *real numbers*.

Theorem. $(\mathbb{R}, <)$ is the unique (up to isomorphism) complete linearly ordered set without endpoints that has a countable subset dense in it.

9. Uncountable Sets

All infinite sets whose cardinalities we have determined up to this point turned out to be countable. Naturally, a question arises whether perhaps all infinite sets are countable. If it were so, this book might end with the preceding section. It was a great discovery of Georg Cantor that uncountable sets, in fact, exist. This discovery provided an impetus for the development of set theory and became a source of its depth and richness.

Theorem The set $\mathbb{R}$ of all real numbers is uncountable.

Proof. Assume that $\mathbb{R}$ is countable, i.e., $\mathbb{R}$ is the range of some infinite sequence $\langle r_n \rangle_{n=1}^{\infty}$. Let $a_0^{(n)}.a_1^{(n)}a_2^{(n)}a_3^{(n)}\cdots$ be the decimal expansion of r_n. Let $b_n = 1$ if $a_n^{(n)} = 0$, $b_n = 0$ otherwise; and let r be the real number whose decimal expansion is $0.b_1b_2b_3\cdots$. We have $b_n \neq a_n^{(n)}$, hence $r \neq r_n$, for all $n = 1, 2, 3, \ldots$, a contradiction. □

The combinatorial heart of the diagonal argument (quite similar to Russell's Paradox, which is of later origin) becomes even clearer in the next theorem.

Theorem. The set of all sets of natural numbers is uncountable; in fact, $|\mathcal{P}(\mathbb{N})| > |\mathbb{N}|$.

Proof. The function $f : \mathbb{N} \mapsto \mathcal{P}(\mathbb{N})$ defined by $f(n) = \{n\}$ is one-to-one, so $|\mathbb{N}| \leq |\mathcal{P}(\mathbb{N})|$. We prove that for every sequence $\langle S_n \mid n \in \mathbb{N}\rangle$ of subsets of $\mathbb{N}$ there is some $S \subseteq \mathbb{N}$ such that $S \neq S_n$ for all $n \in \mathbb{N}$. This shows that there is no mapping of $\mathbb{N}$ onto $\mathcal{P}(\mathbb{N})$, and hence $|\mathbb{N}| < |\mathcal{P}(\mathbb{N})|$.

We define the set $S \subseteq \mathbb{N}$ as follows: $S = \{n \in \mathbb{N} \mid n \notin S_n\}$. The number n is used to distinguish S from S_n: If $n \in S_n$, then $n \notin S$, and if $n \notin S_n$, then $n \in S$. In either case, $S \neq S_n$, as required. □

The set $2^{\mathbb{N}} = \{0, 1\}^{\mathbb{N}}$ of all infinite sequences of 0's and 1's is also uncountable, and, in fact, has the same cardinality as $\mathcal{P}(\mathbb{N})$ and $\mathbb{R}$.

Theorem. $|\mathcal{P}(\mathbb{N})| = |2^{\mathbb{N}}| = |\mathbb{R}|$.

Proof. For each $S \subseteq \mathbb{N}$ define the *characteristic function* of S, $\chi_S : \mathbb{N} \mapsto \{0, 1\}$, as follows:

$$\chi_{S(n)} = \begin{cases} 0 \text{ if } n \in S; \\ 1 \text{ if } n \notin S. \end{cases}$$

It is easy to check that the correspondence between sets and their characteristic functions is a one-to-one mapping of $\mathcal{P}(\mathbb{N})$ onto $\{0,1\}^{\mathbb{N}}$.

To complete the proof, we show that $|\mathbb{R}| \leq |\mathcal{P}(\mathbb{N})|$ and also $|2^{\mathbb{N}}| \leq |\mathbb{R}|$ and use the Cantor-Bernstein Theorem.

a. We have constructed real numbers as cuts in the set **Q** of all rational numbers. The function that assigns to each real number $r = (A, B)$ the set $A \subseteq \mathbf{Q}$ is a one-to-one mapping of $\mathbb{R}$ into $\mathcal{P}(\mathbf{Q})$. Therefore $|\mathbb{R}| \leq |\mathcal{P}(\mathbf{Q})|$. As $|\mathbf{Q}| = |\mathbb{N}|$, we have $|\mathcal{P}(\mathbf{Q})| = |\mathcal{P}(\mathbb{N})|$. Hence $|\mathbb{R}| \leq |\mathcal{P}(\mathbb{N})|$.
b. To prove $|2^{\mathbb{N}}| \leq |\mathbb{R}|$ we use the decimal representation of real numbers. The function that assigns to each infinite sequence $\langle a_n \rangle_{n=0}^{\infty}$ of 0's and 1's the unique real number whose decimal expansion is $0.a_0a_1a_2\cdots$ is a one-to-one mapping of $2^{\mathbb{N}}$ into $\mathbb{R}$. Therefore we have $|2^{\mathbb{N}}| \leq |\mathbb{R}|$.

Zermelo-Fraenkel Set Theory

Axioms of ZF

> **Extensionality**:
> $\forall x \forall y[\forall z(z \in x \equiv z \in y) \rightarrow x=y]$

This axiom asserts that when sets *x* and *y* have the same members, they are the same set.

The next axiom asserts the existence of the empty set:

> **Null Set**:
> $\exists x \forall y(y \notin x)$

Since it is provable from this axiom and the previous axiom that there is a unique such set, we may introduce the notation '∅' to denote it.

The next axiom asserts that if given any set *x* and *y*, there exists a pair set of *x* and *y*, i.e., a set which has only *x* and *y* as members:

> **Pairs**:
> $\forall x \forall y \exists z \forall w(w \in z \equiv w=x \lor w=y)$

Since it is provable that there is a unique pair set for each given *x* and *y*, we introduce the notation '$\{x,y\}$' to denote it.

The next axiom asserts that for any given set *x*, there is a set *y* which has as members all of the members of all of the members of *x*:

> **Unions**:
> $\forall x \exists y \forall z[z \in y \equiv \exists w(w \in x \;\&\; z \in w)]$

Since it is provable that there is a unique 'union' of any set *x*, we introduce the notation '$\bigcup x$' to denote it.

The next axiom asserts that for any set *x*, there is a set *y* which contains as members all those sets whose

members are also elements of x, i.e., y contains all of the subsets of x:

> **Power Set**:
> $\forall x \exists y \forall z[z \in y \equiv \forall w(w \in z \rightarrow w \in x)]$

Since every set provably has a unique `power set', we introduce the notation '$\wp(x)$' to denote it. Note also that we may define the notion x *is a subset of* y ('$x \subseteq y$') as: $\forall z(z \in x \rightarrow z \in y)$. Then we may simplify the statement of the Power Set Axiom as follows:

> $\forall x \exists y \forall z[z \in y \equiv z \subseteq x)$

The next axiom asserts the existence of an infinite set, i.e., a set with an infinite number of members:

> **Infinity**:
> $\exists x[\varnothing \in x \ \& \ \forall y(y \in x \rightarrow \bigcup\{y,\{y\}\} \in x)]$

We may think of this as follows. Let us define *the union of* x *and* y ('$x \cup y$') as the union of the pair set of x and y, i.e., as $\bigcup\{x,y\}$. Then the Axiom of Infinity asserts that there is a set x which contains Ø as a member and which is such that, anytime y is a member of x, then $y \cup \{y\}$ is a member of x. Consequently, this axiom guarantees the existence of a set of the following form:

> $\{\varnothing, \ \{\varnothing\}, \ \{\varnothing, \{\varnothing\}\}, \ \{\varnothing, \{\varnothing\}, \{\varnothing, \{\varnothing\}\}\}, \ \ldots \}$

Notice that the second element, {Ø}, is in this set because (1) the fact that Ø is in the set implies that $\varnothing \cup \{\varnothing\}$ is in the set and (2) $\varnothing \cup \{\varnothing\}$ just is {Ø}. Similarly, the third element, {Ø, {Ø}}, is in this set because (1) the fact that {Ø} is in the set implies that $\{\varnothing\} \cup \{\{\varnothing\}\}$ is in the set and (2) $\{\varnothing\} \cup \{\{\varnothing\}\}$ just is {Ø, {Ø}}. And so forth.

The next axiom asserts that every set is 'well-founded':

> **Regularity**:
> $\forall x[x \neq \varnothing \rightarrow \exists y(y \in x \ \& \ \forall z(z \in x \rightarrow z \notin y))]$

A member y of a set x with this property is called a 'minimal' element. This axiom rules out the existence of circular chains of sets (e.g., such as $x \in y$ & $y \in z$ & and $z \in x$) as well as infinitely descending chains of sets (such as $\ldots x_3 \in x_2 \in x_1 \in x_0$).

The final axiom of ZF is the Replacement Schema. Suppose that $\varphi(x,y,\vec{z})$ is a formula with x and y free, and which may or may not have free variables $z_1,\ldots,z_k$. Furthermore, let $\varphi_{x,y,}\vec{z}[s,r,\vec{z}]$ be the result of substituting s and r for x and y, respectively, in $\varphi(x,y,\vec{z})$. The every instance of the following schema is

an axiom:

> **Replacement Schema**:
> $\forall z_1 \ldots \forall z_k [\forall x \exists! y \varphi(x,y,\vec{z}) \rightarrow \forall u \exists v \forall r (r \in v \equiv \exists s (s \in u \,\&\, \varphi_{x,y,\vec{z}}[s,r,\vec{z}]))]$

In other words, if we know that φ is a functional formula (which relates each set x to a unique set y), then if we are given a set u, we can form a new set v as follows: collect all of the sets to which the members of u are uniquely related by φ.

Note that the Replacement Schema can take you 'out of' the set u when forming the set v. The elements of v need not be elements of u. By contrast, the well-known Separation Schema of Zermelo yields new sets consisting only of those elements of a given set u which satisfy a certain condition ψ. That is, suppose that $\psi(x,\vec{z})$ has x free and may or may not have $z_1,\ldots,z_k$ free. Then the Separation Schema asserts:

> **Separation Schema** $\forall z_1 \ldots \forall z_k [\forall u \exists v \forall r (r \in v \equiv r \in u \,\&\, \psi_{x,\vec{z}}[r,\vec{z}])]$

In other words, if given a formula ψ and a set u, there exists a set v which has as members precisely the members of u which satisfy the formula ψ.

Automated Reasoning

Reasoning is the ability to make inferences, and automated reasoning is concerned with the building of computing systems that automate this process. Although the overall goal is to mechanize different forms of reasoning, the term has largely been identified with valid deductive reasoning as practiced in mathematics and formal logic. In this respect, automated reasoning is akin to mechanical theorem proving. Building an automated reasoning program means providing an algorithmic description to a formal calculus so that it can be implemented on a computer to prove theorems of the calculus in an efficient manner. Important aspects of this exercise involve defining the class of problems the program will be required to solve, deciding what language will be used by the program to represent the information given to it as well as new information inferred by the program, specifying the mechanism that the program will use to conduct deductive inferences, and figuring out how to perform all these computations efficiently. While basic research work continues in order to provide the necessary theoretical framework, the field has reached a point where automated reasoning programs are being used by researchers to attack open questions in mathematics and logic, and to solve problems in engineering.

The Problem Domain

A problem being presented to an automated reasoning program consists of two main items, namely a statement expressing the particular question being asked called the **problem's conclusion**, and a collection of statements expressing all the relevant information available to the program -- the **problem's assumptions**. Solving a problem means proving the conclusion from the given assumptions by the systematic application of rules of deduction embedded within the reasoning program. The problem solving process ends when one such proof is found, when the program is able to detect the non-existence of a proof, or when it simply runs out of resources.

A first important consideration in the design of an automated reasoning program is to delineate the class of problems that the program will be required to solve -- the **problem domain**. The domain can be very large, as would be the case for a general-purpose theorem prover for first-order logic, or be more restricted in scope as in a special-purpose theorem prover for Tarski's geometry, or the modal logic K. A typical approach in the design of an automated reasoning program is to provide it first with sufficient logical power (e.g., first-order logic) and then further demarcate its scope to the particular domain of interest defined by a set of **domain axioms**. To illustrate, EQP, a theorem-proving program for equational logic, was used to solve an open question in Robbins algebra (McCune 1997): *Are all Robbins algebras Boolean?* For this, the program was provided with the axioms defining a Robbins algebra:

(A1)	$x + y = y + x$	(commutativity)
(A2)	$(x + y) + z = x + (y + z)$	(associativity)
(A3)	$-(-(x + y) + -(x + -y)) = x$	(Robbins equation)

The program was then used to show that a characterization of Boolean algebra that uses Huntington's equation,

$$-(-x + y) + -(-x + -y) = x,$$

follows from the axioms. We should remark that this problem is non-trivial since deciding whether a finite set of equations provides a basis for Boolean algebra is undecidable, that is, it does not permit an algorithmic representation; also, the problem was attacked by Robbins, Huntington, Tarski and many of his students with no success. The key step was to establish that all Robbins algebras satisfy

$$(\exists x)(\exists y)(x + y = x),$$

since it was known that this formula is a sufficient condition for a Robbins algebra to be Boolean. When EQP was supplied with this piece of information, the program provided invaluable assistance by completing the proof automatically.

A special-purpose theorem prover does not draw its main benefit by restricting its attention to the domain axioms but from the fact that the domain may enjoy particular theorem-proving techniques which can be hardwired -- coded -- within the reasoning program itself and which may result in a more efficient logic implementation. Much of EQP's success at settling the Robbins question can be attributed to its built-in associative-commutative inference mechanisms.

Language Representation

A second important consideration in the building of an automated reasoning program is to decide (1) how problems in its domain will be presented to the reasoning program; (2) how they will actually be represented internally within the program; and, (3) how the solutions found -- completed proofs -- will be displayed back to the user. There are several formalisms available for this, and the choice is dependent on the problem domain and the underlying deduction calculus used by the reasoning program. The most commonly used formalisms include standard first-order logic, typed λ-calculus, and clausal logic. We take up clausal logic here and assume that the reader is familiar with the rudiments of first-order logic; for the typed λ-calculus the reader may want to check Church 1940. Clausal logic is a quantifier-free variation of first-order logic and has been the most widely used notation within the automated reasoning community. Some definitions are in order: A **term** is a constant, a variable, or a function whose arguments are themselves terms. For example, a, x, $f(x)$, and $h(c,f(z),y)$ are all terms. A **literal** is either an atomic formula, e.g. $F(x)$, or the negation of an atomic formula, e.g. $\sim R(x,f(a))$. Two literals are **complementary** if one is the negation of the other. A **clause** is a (possibly empty) finite disjunction of literals $l_1 \vee \ldots \vee l_n$ where no literal appears more than once in the clause (that is, clauses can be alternatively treated as sets of literals). **Ground** terms, ground literals, and ground clauses have no variables. The **empty clause**, [ ], is the clause having no literals and, hence, is unsatisfiable -- false under any interpretation. Some examples: $\sim R(a,b)$, and $F(a) \vee \sim R(f(x),b) \vee F(z)$ are both examples of clauses but only the former is ground. The general idea is to be able to express a problem's formulation as a set of clauses or, equivalently, as a formula in **conjunctive normal form**, that is, as a conjunction of clauses.

For formulas already expressed in standard logic notation, there is a systematic two-step procedure for transforming them into conjunctive normal form. The first step consists in re-expressing a formula into a semantically equivalent formula in **prenex normal form**, $(\Theta x_1)\ldots(\Theta x_n)\alpha(x_1,\ldots,x_n)$, consisting of a string of quantifiers $(\Theta x_1)\ldots(\Theta x_n)$ followed by a quantifier-free expression $\alpha(x_1,\ldots,x_n)$ called the **matrix**. The second step in the transformation first converts the matrix into conjunctive normal form by using well-known logical equivalences such as DeMorgan's laws, distribution, double-negation, and others; then, the quantifiers in front of the matrix, which is now in conjunctive normal form, are dropped according to certain rules. In the presence of existential quantifiers, this latter step does not always preserve equivalence and requires the introduction of **Skolem functions** whose role is to "simulate" the behaviour of existentially quantified variables. For example, applying the skolemizing process to the formula

$$(\forall x)(\exists y)(\forall z)(\exists u)(\forall v)[R(x,y,v) \vee \sim K(x,z,u,v)]$$

requires the introduction of a one-place and two-place Skolem functions, *f* and *g* respectively, resulting in the formula

$$(\forall x)(\forall z)(\forall v)\ [R(x,f(x),v) \lor \sim K(x,z,g(x,z),v)]$$

The universal quantifiers can then be removed to obtain the final clause, $R(x,f(x),v) \lor \sim K(x,z,g(x,z), v)$ in our example. The Skolemizing process may not preserve equivalence but maintains satisfiability, which is enough for clause-based automated reasoning.

Although clausal form provides a more uniform and economical notation -- there are no quantifiers and all formulas are disjunctions -- it has certain disadvantages. One drawback is the exponential increase in the size of the resulting formula when transformed from standard logic notation into clausal form. The increase in size is accompanied by an increase in cognitive complexity that makes it harder for humans to read proofs written with clauses. Another disadvantage is that the syntactic structure of a formula in standard logic notation can be used to guide the construction of a proof but this information is completely lost in the transformation into clausal form.

Deduction Calculi

A third important consideration in the building of an automated reasoning program is the selection of the actual deduction calculus that will be used by the program to perform its inferences. As indicated before, the choice is highly dependent on the nature of the problem domain and there is a fair range of options available: General-purpose theorem proving and problem solving (first-order logic, simple type theory), program verification (first-order logic), distributed and concurrent systems (modal and temporal logics), program specification (intuitionistic logic), hardware verification (higher-order logic), logic programming (Horn logic), and so on.

A deduction calculus consists of a set of logical axioms and a collection of deduction rules for deriving new formulas from previously derived formulas. Solving a problem in the program's problem domain then really means establishing a particular formula α -- the problem's conclusion -- from the extended set Γ consisting of the logical axioms, the domain axioms, and the problem assumptions. That is, the program needs to determine if $\Gamma \vDash \alpha$. How the program goes about establishing this semantic fact depends, of course, on the calculus it implements. Some programs may take a very **direct** route and attempt to establish that $\Gamma \vDash \alpha$ by actually constructing a step-by-step proof of α from Γ. If successful, this shows of course that Γ derives -- proves -- α, a fact we denote by writing $\Gamma \vdash \alpha$. Other reasoning programs may instead opt for a more **indirect** approach and try to establish that $\Gamma \vDash \alpha$ by showing that $\Gamma \cup \{\sim\alpha\}$ is inconsistent which, in turn, is shown by deriving a contradiction, $\bot$, from the set $\Gamma \cup \{\sim\alpha\}$. Automated systems that implement the former approach include natural deduction systems; the latter approach is used by systems based on resolution, sequent deduction, and matrix connection methods.

Soundness and completeness are two (metatheoretical) properties of a calculus that are particularly

important for automated deduction. **Soundness** states that the rules of the calculus are truth-preserving. For a direct calculus this means that if $\Gamma \vdash \alpha$ then $\Gamma \vDash \alpha$. For indirect calculi, soundness means that if $\Gamma \cup \{\sim\alpha\} \vdash \bot$ then $\Gamma \vDash \alpha$. **Completeness** in a direct calculus states that if $\Gamma \vDash \alpha$ then $\Gamma \vdash \alpha$. For indirect calculi, the completeness property is expressed in terms of **refutations** since one establishes that $\Gamma \vDash \alpha$ by showing the existence of a proof, not of α from Γ, but of $\bot$ from $\Gamma \cup \{\sim\alpha\}$. Thus, an indirect calculus is **refutation complete** if $\Gamma \vDash \alpha$ implies $\Gamma \cup \{\sim\alpha\} \vdash \bot$. Of the two properties, soundness is the most desirable. An incomplete calculus indicates that there are entailment relations that cannot be established within the calculus. For an automated reasoning program this means, informally, that there are true statements that the program cannot prove. Incompleteness may be an unfortunate affair but lack of soundness is a truly problematic situation since an unsound reasoning program would be able to generate false conclusions from perfectly true information.

It is important to appreciate the difference between a logical calculus and its corresponding implementation in a reasoning program. The implementation of a calculus invariably involves making some modifications to the calculus and this results, strictly speaking, in a new calculus. The most important modification to the original calculus is the "mechanization" of its deduction rules, that is, the specification of the systematic way in which the rules are to be applied. In the process of doing so, one must exercise care to preserve the metatheoretical properties of the original calculus.

Two other metatheoretical properties of importance to automated deduction are decidability and complexity. A calculus is **decidable** if it admits an algorithmic representation, that is, if there is an algorithm that, for any given Γ and α, it can determine in a finite amount of time the answer, "Yes" or "No", to the question "Does $\Gamma \vDash \alpha$?" A calculus may be undecidable in which case one needs to determine which decidable fragment to implement. The time-space **complexity** of a calculus specifies how efficient its algorithmic representation is. Automated reasoning is made the more challenging because many calculi of interest are not decidable and have poor complexity measures forcing researchers to seek tradeoffs between deductive power versus algorithmic efficiency.

Resolution

Of the many calculi used in the implementation of reasoning programs, the ones based on the **resolution** principle have been the most popular. Resolution is modeled after the chain rule (of which Modus Ponens is a special case) and essentially states that from $p \vee q$ and $\sim q \vee r$ one can infer $p \vee r$. More formally, let $C - l$ denote the clause C with the literal l removed. Assume that C_1 and C_2 are ground clauses containing, respectively, a positive literal l_1 and a negative literal $\sim l_2$ such that l_1 and $\sim l_2$ are complementary. Then, the rule of **ground resolution** states that, as a result of **resolving** C_1 and C_2, one can infer $(C_1 - l_1) \vee (C_2 - \sim l_2)$:

C_1

C_2

$$\frac{\qquad\qquad}{(C_1 - l_1) \vee (C_2 - \sim l_2)} \quad \text{(ground resolution)}$$

Herbrand's theorem (Herbrand 1930) assures us that the non-satisfiability of *any* set of clauses, ground or not, can be established by using ground resolution. This is a very significant result for automated deduction since it tells us that if a set Γ is not satisfied by any of the infinitely many interpretations, this fact can be determined in *finitely* many steps. Unfortunately, a direct implementation of ground resolution using Herbrand's theorem requires the generation of a vast number of ground terms making this approach hopelessly inefficient. This issue was effectively addressed by generalizing the ground resolution rule to **binary resolution** and by introducing the notion of unification (Robinson 1965a). Unification allows resolution proofs to be “lifted” and be conducted at a more general level; clauses only need to be instantiated at the moment where they are to be resolved. Moreover, the clauses resulting from the instantiation process do not have to be ground instances and may still contain variables. The introduction of binary resolution and unification is considered one of the most important developments in the field of automated reasoning.

Unification

A **unifier** of two expressions -- terms or clauses -- is a substitution that when applied to the expressions makes them equal. For example, the substitution

$$\{x \leftarrow b, y \leftarrow b, z \leftarrow f(a,b)\}$$

is a unifier for

$$R(x,f(a,y)) \text{ and } R(b,z)$$

since when applied to both expressions makes them equal:

$$\begin{aligned} R(x,f(a,y))\{x \leftarrow b, y \leftarrow b, z \leftarrow f(a,b)\} &= R(b,f(a,b)) \\ &= R(b,z)\{x \leftarrow b, y \leftarrow b, z \leftarrow f(a,b)\} \end{aligned}$$

A **most general unifier** (mgu) produces the most general instance shared by two unifiable expressions. In the previous example, the substitution $\{x \leftarrow b, y \leftarrow b, z \leftarrow f(a,b)\}$ is a unifier but not an mgu; however, $\{x \leftarrow b, z \leftarrow f(a,y)\}$ is an mgu. Note that unification attempts to "match" two expressions and this fundamental process has become a central component of most automated deduction programs, resolution-based and otherwise. **Theory-unification** is an extension of the unification mechanism that includes built-in inference capabilities. For example, the clauses $R(g(a,b),x)$ and $R(g(b,a),d)$ do not unify but they AC-unify, where AC-unification is unification with built-in associative and commutative rules such as $g(a,b) = g(b,a)$. Shifting inference capabilities into the unification mechanism adds power but at a

price: The existence of an mgu for two unifiable expressions may not be unique (there could actually be infinitely many), and the unification process becomes undecidable in general.

Binary resolution

Let C_1 and C_2 be two clauses containing, respectively, a positive literal l_1 and a negative literal $\sim l_2$ such that l_1 and l_2 unify with mgu θ. Then,

$$\frac{C_1 \qquad C_2}{(C_1\theta - l_1\theta) \vee (C_2\theta - \sim l_2\theta)} \quad \text{(binary resolution)}$$

by binary resolution; the clause $(C_1\theta - l_1\theta) \vee (C_2\theta - \sim l_2\theta)$ is called a **binary resolvent** of C_1 and C_2.

Factoring

If two or more literals occurring in a clause C share an mgu θ then $C\theta$ is a **factor** of C. For example, in $R(x,a) \vee \sim K(f(x),b) \vee R(c,y)$ the literals $R(x,a)$ and $R(c,y)$ unify with mgu $\{x \leftarrow c, y \leftarrow a\}$ and, hence, $R(c,a) \vee \sim K(f(c),b)$ is a factor of the original clause.

The Resolution Principle

Let $C_1$and C_2 be two clauses. Then, a **resolvent** obtained by **resolution** from C_1 and C_2 is defined as: (a) a binary resolvent of C_1 and C_2; (b) a binary resolvent of C_1 and a factor of C_2; (c) a binary resolvent of a factor of C_1 and C_2; or, (d) a binary resolvent of a factor of C_1 and a factor of C_2.

Resolution proofs, more precisely refutations, are constructed by deriving the empty clause [ ] from $\Gamma \cup \{\sim\alpha\}$ using resolution; this will always be possible if $\Gamma \cup \{\sim\alpha\}$ is unsatisfiable since resolution is refutation complete (Robinson 1965a). As an example of a resolution proof, we show that the set $\{(\forall x)(P(x) \vee Q(x)), (\forall x)(P(x) \supset R(x)),(\forall x)(Q(x) \supset R(x))\}$, denoted by Γ, entails the formula $(\exists x)R(x)$. The first step is to find the clausal form of $\Gamma \cup \{\sim(\exists x)R(x)\}$; the resulting clause set, denoted by S_0, is shown in steps 1 to 4 in the refutation below. The refutation is constructed by using a level-saturation method: Compute all the resolvents of the initial set, S_0, add them to the set and repeat the process until the empty clause is derived. (This produces the sequence of increasingly larger sets: $S_0, S_1, S_2,\ldots$) The only constraint that we impose is that we do not resolve the same two clauses more than once.

S_0	1	$P(x) \vee Q(x)$	Assumption
	2	$\sim P(x) \vee R(x)$	Assumption
	3	$\sim Q(x) \vee R(x)$	Assumption
	4	$\sim R(a)$	Negation of the conclusion
S_1	5	$Q(x) \vee R(x)$	Res 1 2
	6	$P(x) \vee R(x)$	Res 1 3
	7	$\sim P(a)$	Res 2 4
	8	$\sim Q(a)$	Res 3 4
S_2	9	$Q(a)$	Res 1 7
	10	$P(a)$	Res 1 8
	11	$R(x)$	Res 2 6
	12	$R(x)$	Res 3 5
	13	$Q(a)$	Res 4 5
	14	$P(a)$	Res 4 6
	15	$R(a)$	Res 5 8
	16	$R(a)$	Res 6 7
S_3	17	$R(a)$	Res 2 10
	18	$R(a)$	Res 2 14
	19	$R(a)$	Res 3 9
	20	$R(a)$	Res 3 13
	21	[ ]	Res 4 11

Although the resolution proof is successful in deriving [ ], it has some significant drawbacks. To start with, the refutation is too long as it takes 21 steps to reach the contradiction, [ ]. This is due to the naïve brute-force nature of the implementation. The approach not only generates too many formulas but some are clearly redundant. Note how $R(a)$ is derived six times; also, $R(x)$ has more “information content” than $R(a)$ and one should keep the former and disregard the latter. Resolution, like all other automated deduction methods, must be supplemented by strategies aimed at improving the efficiency of the deduction process. The above sample derivation has 21 steps but research-type problems command derivations with thousands or hundreds of thousands of steps.

Resolution Strategies

The successful implementation of a deduction calculus in an automated reasoning program requires the integration of search strategies that reduce the search space by pruning unnecessary deduction paths. Some strategies remove redundant clauses or tautologies as soon as they appear in a derivation. Another strategy is to remove more specific clauses in the presence of more general ones by a process known as **subsumption** (Robinson 1965a). Unrestricted subsumption, however, does not preserve the refutation completeness of resolution and, hence, there is a need to restrict its applicability (Loveland 1978). **Model elimination** (Loveland 1969) can discard a sentence by showing that it is false in some model of the axioms. The subject of model generation has recently received renewed attention as a complementary process to theorem proving. The method has been used successfully by automated reasoning programs to show the independence of axioms sets and to determine the existence of discrete mathematical structures meeting some given criteria.

Instead of removing redundant clauses, some strategies prevent the generation of useless clauses in the first place. The **set-of-support strategy** (Wos, Carson and Robinson 1965) is one of the most powerful strategies of this kind. A subset T of the set S, where S is initially $\Gamma \cup \{\sim\alpha\}$, is called a **set of support** of S iff $S - T$ is satisfiable. Set-of-support resolution dictates that the resolved clauses are not both from $S - T$. The motivation behind set-of-support is that since the set Γ is usually satisfiable it might be wise not to resolve two clauses from Γ against each other. **Hyperresolution** (Robinson 1965b) reduces the number of intermediate resolvents by combining several resolution steps into a single inference step.

Independently co-discovered, **linear resolution** (Loveland 1970, Luckham 1970) always resolves a clause against the most recently derived resolvent. This gives the deduction a simple “linear” structure affording a straightforward implementation; yet, linear resolution preserves refutation completeness. Using linear resolution we can derive the empty clause in the above example in only eight steps:

1	$P(x) \lor Q(x)$	Assumption
2	$\sim P(x) \lor R(x)$	Assumption
3	$\sim Q(x) \lor R(x)$	Assumption
4	$\sim R(a)$	Negation of the conclusion
5	$\sim P(a)$	Res 2 4
6	$Q(a)$	Res 1 5
7	$R(a)$	Res 3 6
8	[ ]	Res 4 7

With the exception of unrestricted subsumption, all the strategies mentioned so far preserve refutation completeness. Efficiency is an important consideration in automated reasoning and one may sometimes be willing to trade completeness for speed. **Unit resolution** and **input resolution** are two such refinements of linear resolution. In the former, one of the resolved clauses is always a literal; in the latter, one of the resolved clauses is always selected from the original set to be refuted. Albeit efficient, neither strategy is complete. Ordering strategies impose some form of partial ordering on the predicate symbols, terms, literals, or clauses occurring in the deduction. **Ordered resolution** treats clauses not as sets of literals but as sequences -- linear orders -- of literals. Ordered resolution is extremely efficient but, like unit and input resolution, is not refutation complete. To end, it must be noted that some strategies improve certain aspects of the deduction process at the expense of others. For instance, a strategy may reduce the size of the proof search space at the expense of increasing, say, the length of the shortest refutations.

There are several automated reasoning programs that are based on resolution, or refinements of resolution. Otter is one of the most versatile among these programs and is being used in a growing number of applications (Wos, Overbeek, Lusk and Boyle 1984). Resolution also provides the underlying logico-computational mechanism for the popular logic programming language Prolog (Clocksin and Mellish 1981).

Sequent Deduction

Hilbert-style calculi (Hilbert and Ackermann 1928) have been traditionally used to characterize logic systems. These calculi usually consist of a few axiom schemata and a small number of rules that typically include modus ponens and the rule of substitution. Although they meet the required theoretical requisites (soundness, completeness, etc.) the approach at proof construction in these calculi is difficult and does not reflect standard practice. It was Gentzen's goal “to set up a formalism that reflects as accurately as possible the actual logical reasoning involved in mathematical proofs” (Gentzen 1935). To carry out this task, Gentzen analyzed the proof-construction process and then devised two deduction calculi for classical logic: the natural deduction calculus, **NK**, and the sequent calculus, **LK**. (Gentzen actually designed NK first and then introduced LK to pursue metatheoretical investigations). The calculi met his goal to a large extent while at the same time managing to secure soundness and completeness. Both calculi are characterized by a relatively larger number of deduction rules and a simple axiom schema. Of the two calculi, LK is the one that has been most widely used in implementations of automated reasoning programs, and it is the one that we will discuss first; NK will be discussed in the next section.

Although the application of the LK rules affect logic formulas, the rules are seen as manipulating not logic formulas themselves but sequents. **Sequents** are expressions of the form $\Gamma \rightarrow \Delta$, where both Γ and Δ are (possibly empty) sets of formulas. Γ is the sequent's **antecedent** and Δ its **succedent**. Sequents can be interpreted thus: Let $\mathfrak{I}$ be an interpretation. Then,

> $\mathfrak{I}$ satisfies the sequent $\Gamma \rightarrow \Delta$ (written as: $\mathfrak{I} \models \Gamma \rightarrow \Delta$) iff

either $\mathfrak{I} \nvDash \alpha$ (for some $\alpha \in \Gamma$) or $\mathfrak{I} \vDash \beta$ (for some $\beta \in \Delta$).

In other words,

> $\mathfrak{I} \vDash \Gamma \rightarrow \Delta$ iff $\mathfrak{I} \vDash (\alpha_1 \,\&\, \ldots \,\&\, \alpha_n) \supset (\beta_1 \vee \ldots \vee \beta_n)$, where $\alpha_1 \,\&\, \ldots \,\&\, \alpha_n$ is the iterated conjunction of the formulas in Γ and $\beta_1 \vee \ldots \vee \beta_n$ is the iterated disjunction of those in Δ.

If Γ or Δ are empty then they are respectively valid or unsatisfiable. An **axiom of LK** is a sequent $\Gamma \rightarrow \Delta$ where $\Gamma \cap \Delta \neq \varnothing$. Thus, the requirement that the same formula occurs at each side of the $\rightarrow$ sign means that the axioms of LK are valid, for no interpretation can then make all the formulas in Γ true and, simultaneously, make all those in Δ false. LK has two rules per logical connective, plus one extra rule: the cut rule.

$\sim\rightarrow$	$\Gamma \rightarrow \Delta, \alpha$ ---- $\Gamma, \sim\alpha \rightarrow \Delta$	$\rightarrow\sim$	$\Gamma, \alpha \rightarrow \Delta$ ----- $\Gamma \rightarrow \Delta, \sim\alpha$
$\exists\rightarrow$	$\Gamma, \alpha(a/x) \rightarrow \Delta$ ------- $\Gamma, (\exists x)\alpha(x) \rightarrow \Delta$	$\exists\rightarrow$	$\Gamma \rightarrow \Delta, \alpha(t/x), (\exists x)\alpha(x)$ ---------- $\Gamma \rightarrow \Delta, (\exists x)\alpha(x)$
$\forall\rightarrow$	$\Gamma, \alpha(t/x), (\forall x)\alpha(x) \rightarrow \Delta$ ---------- $\Gamma, (\forall x)\alpha(x) \rightarrow \Delta$	$\forall\rightarrow$	$\Gamma \rightarrow \Delta, \alpha(a/x)$ ------- $\Gamma \rightarrow \Delta, (\forall x)\alpha(x)$

The sequents above a rule's line are called the **rule's premises** and the sequent below the line is the **rule's conclusion**. The quantification rules $\exists\rightarrow$ and $\rightarrow\forall$ have an eigenvariable condition that restricts their applicability, namely that a must not occur in Γ, Δ or in the quantified sentence. The purpose of this restriction is to ensure that the choice of parameter, a, used in the substitution process is completely "arbitrary".

Proofs in LK are represented as trees where each node in the tree is labeled with a sequent, and where the original sequent sits at the root of the tree. The children of a node are the premises of the rule being applied at that node. The leaves of the tree are labeled with axioms. Here is the LK-proof of $(\exists x)R(x)$ from the set $\{(\forall x)(P(x) \vee Q(x)), (\forall x)(P(x) \supset R(x)),(\forall x)(Q(x) \supset R(x))\}$. In the tree below, Γ stands for this set:

$\Gamma, P(a) \rightarrow P(a), R(a),(\exists x)R(x)$ $\quad$ $\Gamma, P(a), R(a) \rightarrow R(a), (\exists x)R(x)$ $\quad$ $\Gamma, Q(a) \rightarrow Q(a), R(a), (\exists x)R(x)$ $\quad$ $\Gamma, Q(a), R(a) \rightarrow R(a), (\exists x)R(x)$

---------------------------- $\quad$ -----------------------------

$\Gamma, P(a), P(a) \supset R(a) \rightarrow R(a), (\exists x)R(x)$ $\quad$ $\Gamma, Q(a), Q(a) \supset R(a) \rightarrow R(a), (\exists x)R(x)$

--------------- $\quad$ ---------------

$\Gamma, P(a) \rightarrow R(a), (\exists x)R(x)$ $\quad$ $\Gamma, Q(a) \rightarrow R(a), (\exists x)R(x)$

$\Gamma, P(a) \vee Q(a) \rightarrow R(a), (\exists x)R(x)$

$\Gamma, \rightarrow R(a), (\exists x)R(x)$

$\Gamma \rightarrow (\exists x)R(x)$

In our example, all the leaves in the proof tree are labeled with axioms. This establishes the validity of $\Gamma \rightarrow (\exists x)R(x)$ and, hence, the fact that $\Gamma \vDash (\exists x)R(x)$. LK takes an indirect approach at proving the conclusion and this is an important difference between LK and NK. While NK constructs an actual proof (of the conclusion from the given assumptions), LK instead constructs a proof that proves the existence

of a proof (of the conclusion from the assumptions). For instance, to prove that α is entailed by Γ, NK constructs a step-by-step proof of α from Γ (assuming that one exists); in contrast, LK first constructs the sequent $\Gamma \rightarrow \alpha$ which then attempts to prove valid by showing that it cannot be made false. This is done by searching for a counterexample that makes (all the sentences in) Γ true and makes α false: If the search fails then a counterexample does not exist and the sequent is therefore valid. In this respect, proof trees in LK are actually refutation proofs. Like resolution, LK is refutation complete: If $\Gamma \vDash \alpha$ then the sequent $\Gamma \rightarrow \alpha$ has a proof tree.

As it stands, LK is unsuitable for automated deduction and there are some obstacles that must be overcome before it can be efficiently implemented. The reason is, of course, that the statement of the completeness of LK only has to assert, for each entailment relation, the existence of a proof tree but a reasoning program has the more difficult task of actually having to construct one. Some of the main obstacles: First, LK does not specify the order in which the rules must be applied in the construction of a proof tree. Second, and as a particular case of the first problem, the premises in the rules $\forall\rightarrow$ and $\rightarrow\exists$ rules inherit the quantificational formula to which the rule is applied, meaning that the rules can be applied repeatedly to the same formula sending the proof search into an endless loop. Third, LK does not indicate which formula must be selected next in the application of a rule. Fourth, the quantifier rules provide no indication as to what terms or free variables must be used in their deployment. Fifth, and as a particular case of the previous problem, the application of a quantifier rule can lead into an infinitely long tree branch because the proper term to be used in the instantiation never gets chosen. Fortunately, as we will hint at below each of these problems can be successfully addressed.

Axiom sequents in LK are valid, and the conclusion of a rule is valid iff its premises are. This fact allows us to apply the LK rules in either direction, forwards from axioms to conclusion, or backwards from conclusion to axioms. Also, with the exception of the cut rule, all the rules' premises are subformulas of their respective conclusions. For the purposes of automated deduction this is a significant fact and we would want to dispense with the cut rule; fortunately, the cut-free version of LK preserves its refutation completeness (Gentzen 1935). These results provide a strong case for constructing proof trees in a backwards fashion; indeed, by working this way a refutation in cut-free LK gets increasingly simpler as it progresses since subformulas are simpler than their parent formulas. Moreover, and as far as propositional rules go, the new subformulas entered into the tree are completely dictated by the cut-free LK rules. Furthermore, and assuming the proof tree can be brought to completion, branches eventually end up with atoms and the presence of axioms can be quickly determined. Another reason for working backwards is that the truth-functional fragment of cut-free LK is **confluent** in the sense that the order in which the non-quantifier rules are applied is irrelevant: If there is a proof, regardless of what you do, you will run into it! To bring the quantifier rules into the picture, things can be arranged so that all rules have a fair chance of being deployed: Apply, as far as possible, all the non-quantifier rules before applying any of the quantifier rules. This takes care of the first and second obstacles, and it is no too difficult to see how the third one would now be handled. The fourth and fifth obstacles can be addressed by requiring that the terms to be used in the substitutions be suitably selected from the Herbrand universe (Herbrand 1930).

The use of sequent-type calculi in automated theorem proving was initiated by efforts to mechanize

mathematics (Wang 1960). At the time, resolution captured most of the attention of the automated reasoning community but during the 1970's some researchers started to further investigate non-resolution methods (Bledsoe 1977), prompting a frutiful and sustained effort to develop more human-oriented theorem proving systems (Bledsoe 1975, Nevins 1974). Eventually, sequent-type deduction gained momentum again, particularly in its re-incarnation as **analytic tableaux** (Fitting 1990). The method of deduction used in tableaux is essentially cut-free LK's with sets used in lieu of sequents.

Natural Deduction

Although LK and NK are both commonly labeled as “natural deduction” systems, it is the latter which better deserves the title due to its more natural, human-like, approach to proof construction. The rules of NK are typically presented as acting on standard logic formulas in an implicitly understood context, but they are also commonly given in the literature as acting more explicitly on “judgements”, that is, expressions of the form $\Gamma \vdash \alpha$ where Γ is a set of formulas and α is a formula. This form is typically understood as making the metastatement that there is a proof of α from Γ (Kleene 1962). Following Gentzen 1935 and Prawitz 1965 here we take the former approach. The system NK has no logical axioms and provides two introduction-elimination rules for each logical connective:

Introduction Rules ($\odot$I)		Elimination Rules ($\odot$E)	
&I	$\alpha \quad \beta$ ----- $\alpha \,\&\, \beta$	&E	$\alpha_1 \,\&\, \alpha_2$ ---- α_i (for $i = 1,2$)
$\vee$I	α_i (for $i = 1,2$) ---- $\alpha_1 \vee \alpha_2$	$\vee$E	$\alpha \vee \beta$ [α --- γ] [β --- γ] --------- γ
$\supset$I	[α --- β] ----- $\alpha \supset \beta$	$\supset$E	$\alpha \quad \alpha \supset \beta$ ----- β
$\equiv$I	[α --- β] [β --- α] ----- $\alpha \equiv \beta$	$\equiv$E	α_i ($i = 0,1$) $\quad \alpha_0 \equiv \alpha_1$ ---------- α_{1-i}
~I	[α --- $\bot$] ---- $\sim\alpha$	~E	[$\sim\alpha$ --- $\bot$] ---- α
$\exists$I	$\alpha(t/x)$ ---- $(\exists x)\alpha(x)$	$\exists$E	$(\exists x)\alpha(x)$ [$\alpha(a/x)$ --- β] --------- β

∀I	$\alpha(a/x)$ ---- $(\forall x)\alpha(x)$	∀E	$(\forall x)\alpha(x)$ ---- $\alpha(t/x)$

A few remarks: First, the expression [α --- γ] represents the fact that α is an auxiliary assumption in the proof of γ that eventually gets discharged, i.e. discarded. For example, ∃E tells us that if in the process of constructing a proof one has already derived $(\exists x)\alpha(x)$ and also β with $\alpha(a/x)$ as an auxiliary assumption then the inference to β is allowed. Second, the eigenparameter, *a*, in ∃E and ∀I must be foreign to the premises, undischarged -- “active” -- assumptions, to the rule's conclusion and, in the case of ∃E, to $(\exists x)\alpha(x)$. Third, ⊥ is shorthand for two contradictory formulas, β and $\sim\beta$. Finally, NK is complete: If $\Gamma \vDash \alpha$ then there is a proof of α from Γ using the rules of NK.

As in LK, proofs constructed in NK are represented as trees with the proof's conclusion sitting at the root of the tree, and the problem's assumptions sitting at the leaves. (Proofs are also typically given as sequences of judgements, $\Gamma \vdash \alpha$, running from the top to the bottom of the printed page.) Here is a natural deduction proof tree of $(\exists x)R(x)$ from $(\forall x)(P(x) \vee Q(x))$, $(\forall x)(P(x) \supset R(x))$ and $(\forall x)(Q(x) \supset R(x))$:

	$(\forall x)(P(x) \supset R(x))$ ------- $P(a) \supset R(a)$	$(\forall x)(Q(x) \supset R(x))$ ------- $Q(a) \supset R(a)$
$(\forall x)(P(x) \vee Q(x))$ ------- $P(a) \vee Q(a)$	[$P(a)$ --- $R(a)$] ---------- R(a)	[$Q(a)$ --- $R(a)$] ---------- R(a)

$R(a)$

$(\exists x)R(x)$

As in LK, a forward-chaining strategy for proof construction is not well focused. So, although proofs are *read* forwards, that is, from leaves to root or, logically speaking, from assumptions to conclusion, that is not the way in which they are typically *constructed*. A backward-chaining strategy implemented by applying the rules in reverse order is more effective. Many of the obstacles that were discussed above in the implementation of sequent deduction are applicable to natural deduction as well. These issues can be handled in a similar way, but natural deduction introduces some issues of its own. For example, as suggested by the ⊃-Introduction rule, to prove a goal of the form $\alpha \supset \beta$ one could attempt to prove β on the assumption that α. But note that although the goal $\alpha \supset \beta$ does not match the conclusion of any other introduction rule, it matches the conclusion of all *elimination* rules and the reasoning program would need to consider those routes too. Similarly to forward-chaining, here there is the risk of setting goals

that are irrelevant to the proof and that could lead the program astray. To wit: What prevents a program from entering the never-ending process of building, say, larger and larger conjunctions? Or, what is there to prevent an uncontrolled chain of backward applications of, say, ⊃-Elimination? Fortunately, NK enjoys the subformula property in the sense that each formula entering into a natural deduction proof can be restricted to being a subformula of $\Gamma \cup \Delta \cup \{\alpha\}$, where Δ is the set of auxiliary assumptions made by the ~-Elimination rule. By exploiting the subformula property a natural deduction automated theorem prover can drastically reduce its search space and bring the backward application of the elimination rules under control (Portoraro 1998, Sieg and Byrnes 1996). Further gains can be realized if one is willing to restrict the scope of NK's logic to its intuitionistic fragment where every proof has a normal form in the sense that no formula is obtained by an introduction rule and then is eliminated by an elimination rule (Prawitz 1965).

Implementations of automated theorem proving systems using NK deduction have been motivated by the desire to have the program reason with precisely the same proof format and methods employed by the human user. This has been particularly true in the area of education where the student is engaged in the interactive construction of formal proofs in an NK-like calculus working under the guidance of a theorem prover ready to provide assistance when needed (Portoraro 1994, Suppes 1981). Other, research-oriented, theorem provers true to the spirit of NK exist (Pelletier 1998) but are rare.

The Matrix Connection Method

The name of the matrix connection method (Bibel 1981) is indicative of the way it operates. The term “matrix” refers to the form in which the set of logic formulas expressing the problem is represented; the term “connection” refers to the way the method operates on these formulas. To illustrate the method at work, we will use an example from propositional logic and show that R is entailed by $P \vee Q$, $P \supset R$ and $Q \supset R$. This is done by establishing that the formula

$$(P \vee Q) \,\&\, (P \supset R) \,\&\, (Q \supset R) \,\&\, {\sim}R$$

is unsatisfiable. To do this, we begin by transforming it into conjunctive normal form:

$$(P \vee Q) \,\&\, ({\sim}P \vee R) \,\&\, ({\sim}Q \vee R) \,\&\, {\sim}R$$

This formula is then represented as a matrix, one conjunct per row and, within a row, one disjunct per column:

P	Q
$\sim P$	R
$\sim Q$	R
$\sim R$	

The idea now is to explore all the possible vertical paths running through this matrix. A **vertical path** is a set of literals selected from each row in the matrix such that each literal comes from a different row. The vertical paths:

Path 1	*P*, ~*P*, ~*Q* and ~*R*
Path 2	*P*, ~*P*, *R* and ~*R*
Path 3	*P*, *R*, ~*Q* and ~*R*
Path 4	*P*, *R*, *R* and ~*R*
Path 5	*Q*, ~*P*, ~*Q* and ~*R*
Path 6	*Q*, ~*P*, *R* and ~*R*
Path 7	*Q*, *R*, ~*Q* and ~*R*
Path 8	*Q*, *R*, *R* and ~*R*

A path is **complementary** if it contains two literals which are complementary. For example, Path 2 is complementary since it has both *P* and ~*P* but so is Path 6 since it contains both *R* and ~*R*. Note that as soon as a path includes two complementary literals there is no point in pursuing the path since it has itself become complementary. This typically allows for a large reduction in the number of paths to be inspected. In any event, all the paths in the above matrix are complementary and this fact establishes the unsatisfiability of the original formula. This is the essence of the matrix connection method. The method can be extended to predicate logic but this demands additional logical apparatus: Skolemnization, variable renaming, quantifier duplication, complementarity of paths via unification, and simultaneous substitution across all matrix paths (Bibel 1981, Andrews 1981). Variations of the method have been implemented in reasoning programs in higher-order logic (Andrews 1981) and non-classical logics (Wallen 1990).

Term Rewriting

Equality is an important logical relation whose behavior within automated deduction deserves its own separate treatment. **Equational logic** and, more generally, **term rewriting** treat equality-like equations as **rewrite rules**, also known as reduction or demodulation rules. An equality statement like $f(a)= a$ allows the simplification of a term like $g(c,f(a))$ to $g(c,a)$. However, the same equation also has the potential to generate an unboundedly large term: $g(c,f(a))$, $g(c,f(f(a)))$, $g(c,f(f(f(a))))$, … . What distinguishes term rewriting from equational logic is that in term rewriting equations are used as unidirectional reduction rules as opposed to equality which works in both directions. Rewrite rules have the form $t_1 \Rightarrow t_2$ and the basic idea is to look for terms t occurring in expressions e such that t unifies with t_1 with unifier θ so that the occurrence $t_1\theta$ in $e\theta$ can be replaced by $t_2\theta$. For example, the rewrite rule $x + 0 \Rightarrow x$ allows the rewriting of $succ(succ(0) + 0)$ as $succ(succ(0))$.

To illustrate the main ideas in term rewriting, let us explore an example involving symbolic differentiation (the example and ensuing discussion are adapted from Chapter 1 of Baader and Nipkow 1998). Let *der* denote the derivative respect to x, let y be a variable different from x, and let u and v be variables ranging over expressions. We define the rewrite system:

(R1) $der(x) \Rightarrow 1$
(R2) $der(y) \Rightarrow 0$
(R3) $der(u + v) \Rightarrow der(u) + der(v)$
(R4) $der(u \times v) \Rightarrow (u \times der(v)) + (der(u) \times v)$

Again, the symbol $\Rightarrow$ indicates that a term matching the left-hand side of a rewrite rule should be replaced by the rule's right-hand side. To see the differentiation system at work, let us compute the derivative of $x \times x$ respect to x, $der(x \times x)$:

$$\begin{aligned} der(x \times x) &\Rightarrow (x \times der(x)) + (der(x) \times x) && \text{by R4} \\ &\Rightarrow (x \times 1) + (der(x) \times x) && \text{by R1} \\ &\Rightarrow (x \times 1) + (1 \times x) && \text{by R1} \end{aligned}$$

At this point, since none of the rules (R1)-(R4) applies, no further reduction is possible and the rewriting process ends. The final expression obtained is called a **normal form**, and its existence motivates the following question: Is there an expression whose reduction process will never terminate when applying the rules (R1)-(R4)? Or, more generally: Under what conditions a set of rewrite rules will always stop, for any given expression, at a normal form after finitely many applications of the rules? This fundamental question is called the **termination** problem of a rewrite system, and we state without proof that the system (R1)-(R4) meets the termination condition.

There is the possibility that when reducing an expression, the set of rules of a rewrite system could be applied in more than one way. This is actually the case in the system (R1)-(R4) where in the reduction of $der(x \times x)$ we could have applied R1 first to the second sub-expression in $(x \times der(x)) + (der(x) \times x)$, as shown below:

$$\begin{aligned} der(x \times x) &\Rightarrow (x \times der(x)) + (der(x) \times x) && \text{by R4} \\ &\Rightarrow (x \times der(x)) + (1 \times x) && \text{by R1} \\ &\Rightarrow (x \times 1) + (1 \times x) && \text{by R1} \end{aligned}$$

Following this alternative course of action, the reduction terminates with the same normal form as in the previous case. This fact, however, should not be taken for granted: A rewriting system is said to be **(globally) confluent** if and only if independently of the order in which its rules are applied every expression always ends up being reduced to its one and only normal form. It can be shown that (R1)-(R4) is confluent and, hence, we are entitled to say: "Compute *the* derivative of an expression" (as opposed to

simply "*a*" derivative). Adding more rules to a system in an effort to make it more practical can have undesired consequences. For example, if we add the rule

(R5) $u + 0 \Rightarrow u$

to (R1)-(R4) then we will be able to further reduce certain expressions but at the price of losing confluency. The following reductions show that $der(x + 0)$ now has two normal forms:

$$\begin{aligned} der(x + 0) &\Rightarrow der(x) + der(0) && \text{by R3} \\ &\Rightarrow 1 + der(0) && \text{by R1} \end{aligned}$$

$$\begin{aligned} der(x + 0) &\Rightarrow der(x) && \text{by R5} \\ &\Rightarrow 1 && \text{by R1} \end{aligned}$$

Adding the rule, (R6) $der(0) \Rightarrow 0$, would allow the further reduction of $1 + der(0)$ to $1 + 0$ and then, by R5, to 1. Although the presence of this new rule actually increases the number of alternative paths -- $der(x + 0)$ can now be reduced in four possible ways -- they all end up with the same normal form, namely 1. This is no coincidence as it can be shown that (R6) actually restores confluency. This motivates another fundamental question: Under what conditions can a non-confluent system be made into an equivalent confluent one? The Knuth-Bendix **completion** algorithm (Knuth and Bendix 1970) gives a partial answer to this question.

Term rewriting, like any other automated deduction method, needs strategies to direct its application. Rippling (Bundy, Stevens and Harmelen 1993, Basin and Walsh 1996) is a heuristic that has its origins in inductive theorem-proving that uses annotations to selectively restrict the rewriting process.

Mathematical Induction

Mathematical induction is a very important technique of theorem proving in mathematics and computer science. Problems stated in terms of objects or structures that involve recursive definitions or some form of repetition invariably require mathematical induction for their solving. In particular, reasoning about the correctness of computer systems requires induction and an automated reasoning program that effectively implements induction will have important applications.

To illustrate the need for mathematical induction, assume that a property $\wp$ is true of the number zero and also that if true of a number then is true of its successor. Then, with our deductive systems, we can deduce that for any given number n, $\wp$ is true of it, $\wp(n)$. But we cannot deduce that $\wp$ is true of all numbers, $(\forall x)\wp(x)$; this inference step requires the rule of mathematical induction:

$$\frac{\alpha(0) \quad [\alpha(n) \text{ --- } \alpha(succ(n))]}{(\forall x)\alpha(x)} \quad \text{(mathematical induction)}$$

In other words, to prove that $(\forall x)\alpha(x)$ one proves that $\alpha(0)$ is the case, and that $\alpha(succ(n))$ follows from the assumption that $\alpha(n)$. The implementation of induction in a reasoning system presents very challenging search control problems. The most important of these is the ability to determine the particular way in which induction will be applied during the proof, that is, finding the appropriate induction schema. Related issues include selecting the proper variable of induction, and recognizing all the possible cases for the base and the inductive steps.

Nqthm (Boyer and Moore 1979) has been one of the most successful implementations of automated inductive theorem proving. In the spirit of Gentzen, Boyer and Moore were interested in how people prove theorems by induction. Their theorem prover is written in the functional programming language Lisp which is also the language in which theorems are represented. For instance, to express the commutativity of addition the user would enter the Lisp expression (EQUAL (PLUS X Y) (PLUS Y X)). Everything defined in the system is a functional term, including its basic “predicates”: T, F, EQUAL X Y, IF X Y Z, AND, NOT, etc. The program operates largely as a black box, that is, the inner working details are hidden from the user; proofs are conducted by rewriting terms that posses recursive definitions, ultimately reducing the conclusion's statement to the T predicate. The Boyer-Moore theorem prover has been used to check the proofs of some quite deep theorems (Boyer, Kaufmann, and Moore 1995). Lemma caching, problem statement generalization, and proof planning are techniques particularly useful in inductive theorem proving (Bundy, Harmelen and Hesketh 1991).

Higher-Order Logic

Higher-order logic differs from first-order logic in that quantification over functions and predicates is allowed. The statement “*Any two people are related to each other in one way or another*” can be legally expressed in higher-order logic as $(\forall x)(\forall y)(\exists R)R(x,y)$ but not in first-order logic. Higher-order logic is inherently more expressive than first-order logic and is closer in spirit to actual mathematical reasoning. For example, the notion of set finiteness cannot be expressed as a first-order concept. Due to its richer expressiveness, it should not come as a surprise that implementing an automated theorem prover for higher-order logic is more challenging than for first-order logic. This is largely due to the fact that unification in higher-order logic is more complex than in the first-order case: unifiable terms do not always posess a most general unifier, and higher-order unification is itself undecidable. Finally, given that higher-order logic is incomplete, there are always proofs that will be entirely out of reach for any automated reasoning program.

Methods used to automate first-order deduction can be adapted to higher-order logic. TPS (Andrews et

al. 1996) is a theorem proving system for higher-order logic that uses Church's typed λ-calculus as its logical representation language and is based on a connection-type deduction mechanism that incorporates Huet's unification algorithm (Huet 1975). As a sample of the capabilities of TPS, the program has proved automatically that a subset of a finite set is finite, the equivalence among several formulations of the Axiom of Choice, and Cantor's Theorem that a set has more subsets than members. The latter was proved by the program by asserting that there is no onto function from individuals to sets of individuals, with the proof proceeding by a diagonal argument. HOL (Gordon and Melham 1993) is another higher-order proof development system primarily used as an aid in the development of hardware and software safety-critical systems. HOL is based on the LCF approach to interactive theorem proving (Gordon, Milner and Wadsworth 1979), and it is built on the strongly typed functional programming language ML. HOL, like TPS, can operate in automatic and interactive mode. Availability of the latter mode is welcomed since the most useful automated reasoning systems may well be those which place an emphasis on interactive theorem proving (Farmer, Guttman and Thayer 1993) and can be used as assistants operating under human guidance. Isabelle (Paulson 1994) is a generic, higher-order, framework for rapid prototyping of deductive systems. Object logics can be formulated within Isabelle's metalogic by using its many syntactic and deductive tools. Isabelle also provides some ready-made theorem proving environments, including Isabelle/HOL, Isabelle/ZF and Isabelle/FOL, which can be used as starting points for applications and further development by the user. Isabelle/ZF has been used to prove equivalent formulations of the Axiom of Choice, formulations of the Well-Ordering Principle, as well as the key result about cardinal arithmetic that, for any infinite cardinal κ, $\kappa \circ \kappa = \kappa$ (Paulson and Grabczewski 1996).

Non-classical Logics

Non-classical logics such as modal logics, intuitionsitic logic, multi-valued logics, autoepistemic logics, non-monotonic reasoning, commonsense and default reasoning, relevant logic, paraconsistent logic, and so on, have been increasingly gaining the attention of the automated reasoning community. One of the reasons has been the natural desire to extend automated deduction techniques to new domains of logic. Another reason has been the need to mechanize non-classical logics as an attempt to provide a suitable foundation for artificial intelligence. A third reason has been the desire to attack some problems that are combinatorially too large to be handled by paper and pencil. Indeed, some of the work in automated non-classical logic provides a prime example of automated reasoning programs at work. To illustrate, the Ackerman Constant Problem asks for the number of non-equivalent formulas in the relevant logic R. There are actually 3,088 such formulas (Slaney 1984) and the number was found by “sandwiching” it between a lower and an upper limit, a task that involved constraining a vast universe of 20^{400} 20-element models in search of those models that rejected non-theorems in R. It is safe to say that this result would have been impossible to obtain without the assistance of an automated reasoning program.

There have been three basic approaches to automate the solving of problems in non-classical logic (McRobie 1991). One approach has been, of course, to try to mechanize the non-classical deductive calculi. Another has been to simply provide an equivalent formulation of the problem in first-order logic and let a classical theorem prover handle it. A third approach has been to formulate the semantics of the

non-classical logic in a first-order framework where resolution or connection-matrix methods would apply.

Modal logic. Modal logics find extensive use in computing science as logics of knowledge and belief, logics of programs, and in the specification of distributed and concurrent systems. Thus, a program that automates reasoning in a modal logic such as K, K4, T, S4, or S5 would have important applications. With the exception of S5, these logics share some of the important metatheoretical results of classical logic, such as cut-elimination, and hence cut-free (modal) sequent calculi can be provided for them, along with techniques for their automation. Connection methods (Andrews 1981, Bibel 1981) have played an important role in helping to understand the source of redundancies in the search space induced by these modal sequent calculi and have provided a unifying framework not only for modal logics but also for intuitionistic and classical logic as well (Wallen 1990).

Intutionistic logic. There are different ways in which intuitionsitic logic can be automated. One is to directly implement the intuitionistic versions of Gentzen's sequent and natural deduction calculi, LJ and NJ respectively. This approach inherits the stronger normalization results enjoyed by these calculi allowing for a more compact mechanization than their classical counterparts. Another approach at mechanizing intuitionistic logic is to exploit its semantic similarities with the modal logic S4 and piggy back on an automated implementation of S4. Automating intuitionistic logic has applications in software development since writing a program that meets a specification corresponds to the problem of proving the specification within an intuitionistic logic (Martin-Löf 1982). A system that automated the proof construction process would have important applications in algorithm design but also in constructive mathematics. Nuprl (Constable et al. 1986) is a computer system supporting a particular mathematical theory, namely constructive type theory, and whose aim is to provide assistance in the proof development process. The focus is on logic-based tools to support programming and on implementing formal computational mathematics. Over the years the scope of the Nuprl project has expanded from “proofs-as-programs” to “systems-as-theories”.

Logic Programming

Logic programming, particularly represented by the language **Prolog** (Colmerauer et al. 1973), is probably the most important and widespread application of automated theorem proving. During the early 1970s, it was discovered that logic could be used as a programming language (Kowalski 1974). What distinguishes logic programming from other traditional forms of programming is that logic programs, in order to solve a problem, do not explicitly state *how* a specific computation is to be performed; instead, a logic program states *what* the problem is and then delegates the task of actually solving it to an underlying theorem prover. In Prolog, the theorem prover is based on a refinement of resolution known as SLD-resolution. SLD-resolution is a variation of linear input resolution that incorporates a special rule for selecting the next literal to be resolved upon; SLD-resolution also takes into consideration the fact that, in the computer's memory, the literals in a clause are actually ordered, that is, they form a sequence as opposed to a set. A Prolog **program** consists of clauses stating known facts and rules. For example, the following clauses make some assertions about flight connections:

flight(*toronto*, *london*).
flight(*london*,*rome*).
flight(*chicago*,*london*).
flight(*X*,*Y*) :- *flight*(*X*,*Z*) , *flight*(*Z*,*Y*).

The clause *flight*(*toronto*, *london*) is a fact while *flight*(*X*,*Y*) :- *flight*(*X*,*Z*) , *flight*(*Z*,*Y*) is a rule, written by convention as a reversed conditional (the symbol ":-" means "if"; the comma means "and"; terms starting in uppercase are variables). The former states that there is flight connection between Toronto and London; the latter states that there is a flight between cities *X* and *Y* if, for some city *Z*, there is a flight between *X* and *Z* and one between *Z* and *Y*. Clauses in Prolog programs are a special type of Horn clauses having precisely one positive literal: **Facts** are program clauses with no negative literals while **rules** have at least one negative literal. (Note that in standard clause notation the program rule in the previous example would be written as *flight*(*X*,*Y*) ∨ ~*flight*(*X*,*Z*) ∨ ~*flight*(*Z*,*Y*).) The specific form of the program rules is to effectively express statements of the form: "I*f these conditions over here are jointly met then this other fact will follow*". Finally, a **goal** is a Horn clause with no positive literals. The idea is that, once a Prolog program Π has been written, we can then try to determine if a new clause γ, the goal, is entailed by Π, $\Pi \vDash \gamma$; the Prolog prover does this by attempting to derive a contradiction from $\Pi \cup \{\sim\gamma\}$. We should remark that program facts and rules alone cannot produce a contradiction; a goal must enter into the process. Like input resolution, SLD-resolution is not refutation complete for first-order logic but it is complete for the Horn logic of Prolog programs. The fundamental theorem: If Π is a Prolog program and γ is the goal clause then $\Pi \vDash \gamma$ iff $\Pi \cup \{\sim\gamma\} \vdash$ [ ] by SLD-resolution (Lloyd 1984).

For instance, to find out if there is a flight from Toronto to Rome one asks the Prolog prover to see if the clause *flight*(*toronto*, *rome*) follows from the given program. To do this, the prover adds ~*flight*(*toronto*, *rome*) to the program clauses and attempts to derive the empty clause, [ ], by SLD-resolution:

1	*flight*(*toronto*,*london*)	Program clause
2	*flight*(*london*,*rome*)	Program clause
3	*flight*(*chicago*,*london*)	Program clause
4	*flight*(*X*,*Y*) ∨ ~*flight*(*X*,*Z*) ∨ ~*flight*(*Z*,*Y*)	Program clause
5	~*flight*(*toronto*,*rome*)	Negation of the conclusion
6	~*flight*(*toronto*,*Z*) ∨ ~*flight*(*Z*,*rome*)	Res 5 4
7	~*flight*(*london*,*rome*)	Res 6 1
8	[ ]	Res 7 2

The conditional form of rules in Prolog programs adds to their readability and also allows reasoning about the underlying refutations in a more friendly way: To prove that there is a flight between Toronto and Rome, *flight*(*toronto*,*rome*), unify this clause with the consequent *flight*(*X*,*Y*) of the fourth clause in

the program which itself becomes provable if both *flight*(*toronto*,*Z*) and *flight*(*Z*,*rome*) can be proved. This can be seen to be the case under the substitution $\{Z \leftarrow london\}$ since both *flight*(*toronto*,*london*) and *flight*(*london*,*rome*) are themselves provable. Note that the theorem prover not only establishes that there is a flight between Toronto and Rome but it can also come up with an actual itinerary, Toronto-London-Rome, by extracting it from the unifications used in the proof.

There are at least two broad problems that Prolog must address in order to achieve the ideal of a logic programming language. Logic programs consist of facts and rules describing what is true; anything that is not provable from a program is deemed to be false. In regards to our previous example, *flight*(*toronto*, *boston*) is not true since this literal cannot be deduced from the program. The identification of falsity with non-provability is further exploited in most Prolog implementations by incorporating an operator, **not**, that allows programmers to explicitly express the negation of literals (or even subclauses) within a program. By definition, not *l* succeeds if the literal *l* itself fails to be deduced. This mechanism, known as **negation-by-failure**, has been the target of criticism. Negation-by-failure does not fully capture the standard notion of negation and there are significant logical differences between the two. Standard logic, including Horn logic, is monotonic which means that enlarging an axiom set by adding new axioms simply enlarges the set of theorems derivable from it; negation-by-failure, however, is non-monotonic and the addition of new program clauses to an existing Prolog program may cause some goals to cease from being theorems. A second issue is the **control problem**. Currently, programmers need to provide a fair amount of control information if a program is to achieve acceptable levels of efficiency. For example, a programmer must be careful with the order in which the clauses are listed within a program, or how the literals are ordered within a clause. Failure to do a proper job can result in an inefficient or, worse, non-terminating program. Programmers must also embed hints within the program clauses to prevent the prover from revisiting certain paths in the search space (by using the **cut** operator) or to prune them altogether (by using **fail**). Last but not least, in order to improve their efficiency, many implementations of Prolog do not implement unification fully and bypass a time-consuming yet critical test -- the so-called occurs-check -- responsible for checking the suitability of the unifiers being computed. This results in an unsound calculus and may cause a goal to be entailed by a Prolog program (from a computational point of view) when in fact it should not (from a logical point of view).

There are variations of Prolog intended to extend its scope. By implementing a model elimination procedure, the Prolog Technology Theorem Prover (PPTP) (Stickel 1992) extends Prolog into full first-order logic. The implementation achieves both soundness and completeness. Moving beyond first-order logic, λProlog (Miller and Nadathur 1988) bases the language on higher-order constructive logic.

Conclusion

Automated reasoning is a growing field that provides a healthy interplay between basic research and application. Automated deduction is being conducted using a multiplicity of theorem-proving methods, including resolution, sequent calculi, natural deduction, matrix connection methods, term rewriting, mathematical induction, and others. These methods are implemented using a variety of logic formalisms such as first-order logic, type theory and higher-order logic, clause and Horn logic, non-classical logics,

and so on. Automated reasoning programs are being applied to solve a growing number of problems in formal logic, mathematics and computer science, logic programming, software and hardware verification, circuit design, and many others. One of the results of this variety of formalisms and automated deduction methods has been the proliferation of a large number of theorem proving programs. To test the capabilities of these different programs, selections of problems has been proposed against which their performance can be measured (McCharen, Overbeek and Wos 1976, Pelletier 1986). The TPTP (Sutcliffe and Suttner 1998) is a library of such problems that is updated on a regular basis. There is also a competition among automated theorem provers held regularly at the CADE conference; the problems for the competition are selected from the TPTP library.

Initially, computers were used to aid scientists with their complex and often tedious numerical calculations. The power of the machines was then extended from the numeric into the symbolic domain where infinite-precision computations performed by computer algebra programs have become an everyday affair. The goal of automated reasoning has been to further extend the machine's reach into the realm of deduction where they can be used as reasoning assistants in helping their users establish truth through proof.

Giles of Rome

Giles of Rome (who died in 1316 as archbishop of Bourges) was one of the most productive and influential thinkers active at the end of the 13th century, who played a major role also in the political events of his time. Giles of Rome was an extremely prolific author and left a very large corpus of writings, encompassing commentaries on Aristotle, theological treatises, questions, and sermons. In recent years, a research group led by Francesco Del Punta (Scuola Normale Superiore, Pisa, Italy) has been devoting a lot of energy to the project of publishing his *Opera Omnia* and deepening our knowledge of his thought. Although this group has produced extremely significant results, an assessment of Giles' whole work is still in progress. For this reason, the present entry only aims at providing insight into an ongoing process of research and will focus on recent studies on Giles.

Life

Born in Rome most probably in the fifth decade of the thirteenth century, Giles was the first outstanding theologian of the relatively recently founded Order of the Augustinian Hermits. Nothing more is known about his origins: the statement that he belonged to the famous Roman family of the Colonna seems to go back to Jordan of Saxony's *Liber Vitasfratrum* (second half of the 14th century), but is completely missing from contemporary, 13th-century sources. From Giles' will we know that he was sent to Paris to study in the convent of his Order. At the beginning he must have followed the courses either of a secular master or of a theologian belonging to a different Order, as the Augustinian friars did not have a regent master at the time. Probably he was a pupil of Aquinas' in the years 1269-1272. He commented on the Sentences at the beginning of the 1270's. In following years he probably wrote also a large number of his commentaries on Aristotle.

The year 1277 marked a turning-point in his career: Giles was involved in the condemnation of the heterodox Aristotelianism issued by the Parisian bishop Etienne Tempier, although the process against him must be distinguished from the famous decree of the 7 of March 1277, as Robert Wielockx has shown. After 1277 Giles must have abandoned Paris, but his presence is attested in Italy not earlier than 1281. Before leaving Paris he completed his De regimine principum, which is dedicated to the young Philip, the future Philip the Fair.

Between 1281 and 1284 Giles played an important role in the government of his Order, taking part in various chapters held in Italy. At the provincial chapter of Tuscania (nowadays in Lazio, Italy) in 1285 he acted as vicar of the prior general of his Order, Clement of Osimo.

In 1285, Giles'doctrine was examined again; after recanting only a part of what had been previously condemned in 1277, he was allowed to teach again; by 1287 he is referred to as a master of theology. This success enhanced Giles of Rome's authority even more in his Order, whose general chapter of Florence decreed that Giles' works (even future ones) should be considered as the official doctrine of the Order, to be defended by all Augustinian bachelors and masters. In 1292, at the General Chapter of Rome he was elected prior general of his Order.

Benedict Caetani's election to the papal see marked a further radical change in his career, as Boniface VIII appointed him archbishop of Bourges in 1295. As a matter of fact, Giles was very often absent from his see, spending extended periods of time at the papal curia. In his *De renuntiatione*, he defended the legitimacy of Celestine's abdication, and, consequently, of Boniface' s election. When the contrast between Boniface VIII and Philip IV reached its most critical point, he continued to side staunchly with the pope. An important sermon defending the papal position has been recently discovered by Concetta Luna, and Giles' *De ecclesiastica potestate* undoubtedly ranks among the sources of *Unam Sanctam*.

Giles' prestige decreased after Boniface' death, and even more with the rise of Clement V to the papal throne. Before being elected pope, Betrand de Got, as archbishop of Bourdeaux, had had serious conflicts with Giles. This unfavorable change, however, did not prevent Giles from playing a significant role in the debates of his time. Around 1305-6 he took part in a commission which examined and condemned the eucharistic doctrine of John of Paris, a former adversary of Giles' during the conflict between Philip the Fair and Boniface. In the discussions concerning the Templars which eventually led to the violent suppression of the Order, Giles sided with Philip the Fair, attacking the Templars and devoting a whole tract, *Contra exemptos*, to the thesis that their exemption from episcopal jurisdiction was the cause of their abuses. During the Council of Vienne Giles was asked to draw a list of errors extracted from the works of Peter John Olivi: three of them were officially condemned by the Council. On December 22, 1316 he died at the papal Curia at Avignon (For further details see Del Punta-Donati-Luna 1993).

Logic and Rhetoric

After René Antoine Gauthier identified in the master Guillaume Arnauld the real author of the *Lectura*

supra logicam veterem attributed to Giles of Rome (Tabarroni 1988), interest in logical works focused mainly on his Commentary on the *Sophistici Elenchi*. In his treatment of the *fallacia figurae dictionis* Giles proves to be a brilliant and original representative of “modistic logic”, who bases his solutions mainly on the semantics of *intentiones* (Tabarroni 1991). Alessandro Conti (1992) investigated Giles’ Commentary on *Posterior Analytics* as an example of his theory of truth, which brings to completion Aquinas’ shift from Augustine’s influence to the Aristotelian approach . Giles of Rome also authored the most important Commentary on the Rhetoric of the Latin medieval tradition, which earned him the honorific title of *expositor* of this book and influenced all later medieval commentaries. Costantino Marmo studied Giles’ approach to the different translations to which he had access and showed how he developed Aquinas’ theory of passions in commenting on the relevant portions of Aristotle’s text (Marmo 1991), trying to solve some problems left open by Aquinas. It has been suggested that Giles considers rhetoric to be a sort of “logic” of ethics and politics: this brilliant interpretation still awaits, however, full development and articulation (Staico 1992).

Metaphysics

Traditionally, Giles was described as a “faithful” disciple of Aquinas’. As a matter of fact, his “philosophical project” tends to discuss critically Aquinas’ position in order to improve the solutions he offered, without, however, trying to discard them radically. This holds true, e. g., for one of the most famous topics of his discussion with Henry of Ghent, the distinction between “essence” and “existence”. In this case, Giles radicalizes Aquinas’ doctrine of the real distinction, asserting that existence must be conceived as a “*res addita*” to essence. Although the final result of his theory was considered closer to Avicenna’s solution than to that of Aquinas, Giles nevertheless develops it starting from Aquinas’ own position (Wippel 1981). The connection of this issue with the discussion with Henry of Ghent about the concept of “creation” was deeply investigated by Giorgio Pini (1992), who could show how Giles, while defending Aquinas and thereby the possibility of using some Aristotelian principles in an orthodox account of creation, goes beyond the positions of the Dominican master, e. g. asserting the identity of “*esse*” and “*creatio*”.

As to the debate about the unicity of substantial form, Giles’ position evolves during time. If we leave aside the *Errores philosophorum*, since the authenticity of this work has been contested with serious arguments (Bruni 1935, Koch 1944, Donati 1990b, Luna 1990), we can notice that Giles changes his position from the *Contra gradus et pluralitatem formarum* (between the end of 1277 and the beginning of 1278), where he denies plurality of forms for every compound, to later works, where he takes a more cautious stance in particular concerning man. The principle of individuation is identified, as in Aquinas, with “materia signata quantitate”, that is, matter designated by its dimensions. According to Giles, who criticizes Richard of Mediavilla on this point, matter is pure potentiality and therefore cannot be distinguished into different kinds. For this reason, he cannot accept Aquinas’ doctrine that the incorruptibility of celestial bodies derives from the peculiar nature of their matter (Donati 1986). In Giles’ opinion celestial bodies are not incorruptible because their matter is different from the matter of sublunar bodies, but rather because their *quantitas materiae* cannot change its determinate dimensions. This is but one application of Giles’ famous doctrine of “indeterminate dimensions”. Modifying

Averroes' doctrine in this respect, Giles argues that a portion of matter, in order to be able to receive a form, needs to possess already a sort of quantity. Such quantity, however, should not be identified with the determinate dimensions a body possesses, but is rather a *quantitas* which remains the same during processes such as rarefaction and condensation. Giles' notion of *quantitas materiae* , which is not only generically extension or three-dimensionality, but seems to represent an unchangeable given "amount" of matter pertaining to a body, has been considered comparable, some difficulties notwithstanding, to the modern notion of mass (Donati 1988).

After the condemnation of 1277, a significant change can be noticed in Giles' position also in his solution of the problem of the eternity of the world. At the beginning of his career he admitted the theoretical possibility of the eternity of the world, although rejecting Aristotle's arguments proving the actual eternity of the world. Later he shifted to a more " Augustinian" stance, rejecting the hypothesis of a creation "*ab aeterno*" and admitting that it is possible to prove the temporality of creation, although he finds that no conclusive argument has been advanced so far. Giles was much more steadfast in his opposition to another major tenet of "Averroistic" doctrine, that is the unicity of the possible intellect. He maintained that the possibility of actual knowledge on the part of the individual depends necessarily on the fact that each body is informed by its own intellective soul, which is its form. For the same reasons Giles also rejected the unicity of the agent intellect, a doctrine he attributed to Avicenna (Del Punta-Donati-Luna 1993).

Natural Philosophy

Recent studies concerning Giles' natural philosophy focused mainly on his treatment of some pivotal concepts of Aristotle's Physics. Cecilia Trifogli opened new perspectives in this field, devoting her attention to the notions of place and motion (especially in the void, see Trifogli 1992), underlining that "Giles' emphasis on the role of place in the description of motion seems to lead to a quantitative and relational notion of place. Giles, however, does not completely substitute the Aristotelian notion of place for that of place as distance. Place as distance is only one of the two notions of place which appear in his commentary. The other, which is related to material place, assumes an intrinsic connection between place and the located body that cannot be founded on distance alone" (Trifogli 1990a, 350). Trifogli also investigated Giles' notions of time and infinity, emphasizing that his whole approach to natural philosophy is distinguished by a tendency towards a metaphysical interpretation of Aristotelian concepts, as opposed to a physical and quantitative one (Trifogli 1990b, 1991). For example, Giles conceives of time not as a quantity pertaining to every kind of motion, but rather as a mode in which motion exists. His concept of time rests in fact essentially on a broad notion of succession, which allows him on one hand to retain the unity of the concept of time, but, on the other hand, to acknowledge the existence of different temporal forms (Trifogli 1990b). This attitude emerges also from the analysis of Giles' controversy on angelic time with Henry of Ghent (Porro 1988, Porro 1991, but see also Faes de Mottoni 1983). Both authors thought that the time in which angels exist, unlike sublunar time, is a discrete succession of instants. Giles and Henry disagreed, however, on the relationship existing between angelic and sublunar time. In particular, Henry rejected Giles' thesis that more instants of angelic time can correspond to one and the same instant of sublunar time. This difference of opinion rested in part on

diverging concepts of angelic motion, which can be istantaneous according to Henry, but not according to Giles.

Between Philosophy and Medicine

Between 1285 and 1290, Giles took a stance in the much debated question of the respective roles of male and female parents in conception. The Galenist view, going back to Hippocrates, was that both male and female contributed sperm, so that the offspring could have characteristics from both parents. On the contrary, Aristotle had held that only the male alone contributed sperm containing an active and formal principle to conception, while the female provided only the matter of the fetus. Giles was well acquainted with these different positions and with the efforts to reconcile the diverging approaches of *medici* and *philosophi*, which could be traced back to Avicenna. Leaning on Averroes' *Colliget*, however, Giles rejected any attempt to attribute a formal role to the female sperm, even if it is conceived as subordinate to the male one. On the contrary he maintained that it can contribute only in a passive way to conception, while what was called "female sperm", i.e., the vaginal secretion, has a subservient, helpful but by no means necessary function. It helps the male sperm to inseminate female matter, but does not add anything essential to the new being. In this way, Giles intended to stress the superiority of the philosophical, theoretical approach to such problems with respect to the traditions of medical learning, even when they seemed to be supported by empirical evidence (Hewson 1975; Martorelli Vico 1988). After conception the human embryo begins a development which goes through different stages. Comparing these stages to the embryos of various animals Giles, like Thomas Aquinas, supported an interpretation of the fetal development which would be exploited many centuries later by the so-called "recapitulation theory" (Hewson 1975, 99). Giles maintained, however, that "the organic fetal body is not to be called a pig, a bear, or a monkey, but something immediately disposed to becoming man" (Hewson 1975, 100). This position apparently implies that human life does not fully begin at the moment of conception. Although such a thesis can be brought to bear on the moral judgment concerning abortion, Giles does not seem interested in tackling from this point of view an issue which would become central for what nowadays is called bioethics.

Ethics and Political Theory

In the debate on the respective roles of intellect and will in the determination of human action Giles is known to have taken and intermediate position, a sort of compromise between the theory of Henry of Ghent and that of Geoffrey of Fontaines. Giles maintains, in fact, that will is a passive potency and can not "move" itself, but always needs an object, a "bonum apprehensum". This starting point however, does not rule out its freedom, because will, once "moved" by its object, can determine itself and other potencies with regard to action. This view of Giles' is consistent with his interpretation of the relationship existing between knowledge and will in the sinner. Committing a sin implies an ignorance of the real good, but this ignorance is not the primary cause of the wrong behavior, because it is an effect of the will, which, affected by *malicia*, corrupts the judgment of the reason (Macken 1977).

Giles of Rome exerted considerable influence also in other fields of ethics, such as the theory of virtues. The most developed expression of his position is not to be found in a Commentary on Aristotle, but rather in his *De regimine principum*, the most successful “mirror of princes” of medieval political thought, which is still conserved in more than 300 manuscripts in its original Latin version, to which many translations in European vernaculars must be added. Written most probably between 1277 and 1280 the *De regimine* is acknowledged to be one of the most successful attempts at mediating Aristotle’s practical philosophy, and in particular his “ethical and political language” to the Latin West. Giles was the first to structure a mirror of princes in three books along the lines of a scheme -- *ethica-oeconomica-politica* -- which played an important role in the reception of Aristotle’s moral and political philosophy in the Middle Ages (Lambertini 1988). The author takes great care to give the impression that he is mainly relying on Aristotle’s text, providing numerous quotations from the *Nichomachean Ethics*, from the *Politics* and from the *Rethoric*. Scholars should not overlook, however, that his reception of Aristotle is not as direct as it can seem and that Giles is deeply influenced by a tradition in the interpretation of Aristotle’s practical philosophy. In this tradition Aquinas plays a very important role for Giles, so that, while Aristotle is the authority who is quoted on almost every occasion, it is the unnamed Aquinas who, with his *Sententia libri Politicorum*, *De regno*, *Summa Theologiae*, exerts a really decisive influence on *De regimine*. While discussing particular topics, Giles skillfully adapts Aristotle to his own purposes. This emerges with clarity in the first book, devoted to ethics, where Giles’ classification of virtues is heavily dependent on the *Summa Theologiae* and, therefore, on Aquinas’ reinterpretation of the Aristotelian heritage. For example, Giles here defines *prudentia* as a *virtus media*, sharing the nature of moral as well as of intellectual ones, a doctrine which can by no means be traced back to the Stagirite (Lambertini 1991, 1992, 1995, 2000).

The most famous example of this selective attitude towards Aristotle’s works, however, belongs rather to the field of political theory. In the third book of *De regimine* Giles wants to prove that Monarchy is the absolutely best form of government. The first arguments he puts forward in favor of monarchy are not taken from Aristotle’s *Politics*, but from Aquinas’ *De regno*. Then some arguments against monarchy which could be read in the *Politics* are presented as objections that Aristotle puts forth for subsequent refutation. At the end, Giles states squarely that Aristotle supports monarchy as the absolutely best form of monarchy and corroborates his assertion with an argument, which, in the *Politics*, actually goes in the opposite direction (Lambertini 1990). One could provide several other examples to show that the *De regimine* succeeded in presenting itself as a simplified exposition and explanation of Aristotle’s thought in practical philosophy, but at the same time transmitted to Giles’ readers a strongly biased interpretation of the Stagirite. The fact that the *De regimine* was often used as a tool to have easier access to Aristotle’s political theory deeply influenced, therefore, the way the Latin West read and understood Aristotle’s *Politics* in the Late Middle Ages. Recent codicological studies on the diffusion of *De regimine’* manuscripts do in fact show that many possessors of the manuscripts most probably used them for study (See *Opera Omnia* I.1/11, *Catalogo dei manoscritti, De regimine*; Briggs 1999).

While in the *De regimine* Giles carefully avoids any reference to the thorny problem of the relationship between secular and ecclesiastical power, his later writings which are relevant for political theory deal first and foremost with ecclesiological problems. This holds true for his treatise *De renuntiatione papae* (1297-1298) where Giles defends the lawfulness of Celestine’s abdication against the arguments put

forward by the Colonna cardinals in their first appeal against Boniface VIII. From the point of view of the history of political thought it is relevant that Giles argues that papal power, although of divine origin, is conferred on a particular individual by a human act, namely, by the election of the cardinals. Here Giles is countering the Colonna arguments that papal dignity cannot cease to reside in a pope until he dies, because the pontificate depends on God's will, and stresses the fact that divine intention in this case becomes effective through the mediation of human agents, that is, through the consent of the electors and of the elected. A jurisdiction which is given by the consent of men, however, can also be removed by their consent through a reverse procedure. This does not amount to saying that the pope can be deposed (except in case of heresy), because, according to Giles, the pope is above the law and has no earthly authority above him. He can however, depose himself, that is, abdicate. Just as for his election the consent of his electors and of the elected was necessary, so also for the removal of the pope from office his consent is decisive (Eastman 1989, 1990, 1992). In this way Giles could dismiss arguments against the validity of Celestine's abdication without admitting the possibility that the pope can be deposed, e. g., by the Council, as Boniface's adversaries maintained.

Much better known than *De renuntiatione* is Giles' *De ecclesiastica potestate*, a treatise also composed in defense of Boniface VIII. Most probably in 1302, Giles systematically expounded in this work the views on the relationship between *regnum* and *sacerdotium* he had already put forward in a recently re-discovered sermon held at the papal curia (Luna 1992). The main tenet of his fully fledged argumentation is that the pope, supreme authority of the Church but also of the whole of mankind, is the only legitimate origin of every power on earth, be it exercised -- as jurisdiction -- on persons, or -- as property -- on things. In his plenitude of power, the pope possesses an absolute supremacy both in the ecclesiastical and in the temporal sphere, and delegates the exercise of the temporal "sword" to lay sovereigns only in order to fulfill most properly his higher religious duties. Any authority that does not recognize its dependence on the papal power is but usurpation. In Giles' view, there is no space even for a partially autonomous temporal order. Coherently, Giles maintains that no property rights are valid if they are not legitimated by papal authority. Interestingly enough, such a claim is also supported by his account of the origin of property, according to which property is not a natural institution, but only the consequence of human agreements, which lack any legitimacy unless they are recognized by the supreme religious power (Miethke 2000).

Bibliography

Primary Sources

The most complete list of Giles' works can be found in Del Punta--Donati--Luna 1993 together with the most reliable attempt at dating them (see also Donati 1990b as far as commentaries on Aristotle are concerned). The same article by Del Punta, Donati and Luna also contains the best available bibliography, which can be complemented with Lezcano 1995, 32-50.It is impossible to reproduce all that information in the present entry. Standard older editions were reprinted in Frankfurt 1967-1970. Among the texts edited in our century I would mention the following:

- *De ecclesiastica potestate*, ed. R. Scholz, Weimar 1929 (English translation in R. W. Dyson, *Giles of Rome on Ecclesiastical Power. The De ecclesiastica potestate of Aegidius Romanus*, Woodbridge 1986)
- *Theoremata de esse et essentia*, ed. H.Hocedez, Louvain 1930
- *De differentia ethicae, politicae et rhetoricae*, ed. G. Bruni, *The New Scholasticism* 6 (1932), 5-12.

Paul of Venice

Paul of Venice was the most important Italian thinker of his times, and one of the most prominent and interesting logicians of the Middle Ages. His philosophical theories (culminating in a metaphysics of essences which states the ontological and epistemological primacy of universals over any other kind of beings) are the final and highest result of the preceding realistic tradition of thought. He fully developed the new form of realism started up by Wyclif and his Oxonian followers in the last decades of the 14th century, and renewed Burley's attacks against nominalistic views. The metaphysical convictions at the basis of his philosophy are an original version of the most fundamental theses of Duns Scotus (viz. univocity of being; existence of universal forms outside the mind, which are at the same time identical with and different from their own individuals; real identity and formal distinction between essence and being; thisness as the principle of individuation; real distinction among the ten categories). But Paul puts much more stress on the ontological presuppositions and entailments of the doctrine. Simultaneously, he was open to influences from many other directions, as he held in due consideration also the positions of authors such as Albert the Great, Thomas Aquinas, and Giles of Rome, and critically discussed the doctrines of the main Nominalists of the 14th century, namely William Ockham, John Buridan, and Marsilius of Inghen, sometimes playing mutually incompatible theses against each other. This contributes to making his works stimulating and enriching from an historical point of view, but also makes it difficult to grasp his own ideas in their relationships and unity. These reflections help us to explain why for about one hundred and fifty years Paul was erroneously, but unanimously, believed to be an Ockhamist in logic and metaphysics and an Averroist in psychology and epistemology.

---

1. Life and Works

Paul of Venice (Paulus Nicolettus Venetus, Paolo Nicoletti Veneto), O.E.S.A. was born in Udine, Italy,

around 1369. He joined the Augustinian order near the age of fourteen, when he entered the convent of Santo Stefano in Venice. He studied first at Padua, but in 1390 he was assigned to Oxford, where he spent three years. He became Doctor of Arts and Theology by 1405. He taught in Padua, Siena (1420-24), and Perugia (1424-28), and lectured in Bologna (1424). At various times he held positions of leadership in his order (Pope Gregory XII designated him Prior General of the Augustinians in May 1409) and served as ambassador of the Venetian Republic. He died in Padua on 15 June 1429, while commenting the *De anima* (*On the Soul*) of Aristotle.

Paul wrote many philosophical and theological treatises (the complete list of his writings and a guide to extant manuscripts are in Perreiah 1986; for the dating of his main philosophical works see Conti 1996, pp. 9-20), including: *Logica parva* (*The Small Logic*), ca. 1393-95; *Logica magna* (*The Great Logic*), ca. 1396-99; *Sophismata aurea* (*Golden Sophisms*), ca. 1399; a commentary on Aristotle's *Posterior Analytics* (*In Post*.), A.D. 1406; *Summa philosophiae naturalis* (*Summa of Natural Philosophy -- SN*), A.D. 1408; a commentary on Aristotle's *Physics* (*In Phys*.), A.D. 1409; a commentary on Aristotle's *On the Soul* (*In De anima*), ca. 1415-20; *Quaestio de universalibus* (*On Universals -- QdU*), ca. 1420-24; a commentary on Aristotle's *Metaphysics* (*In Metaph*.), ca. 1420-24; a commentary on the *Ars Vetus*, that is, on Porphyry's *Isagoge*, Aristotle's *Categories*, and the *Liber sex principiorum* (*Expositio super Universalia Porphyrii et Artem Veterem Aristotelis -- In Porph*., *In Cat*., and *In Sex pr*. respectively), A.D. 1428.

2. Logic

The main contributions of Paul of Venice to the history of logic in the Middle Ages concern the notion of formal distinction and the analysis of predication.

2.1 Identities and Distinctions

Paul's formulation of the theory of identity and distinction is a further development of Duns Scotus' and Wyclif's doctrines on the subject. The Italian master recognizes two main types of identity: material (*secundum materiam*) and formal (*secundum formam*). There is material identity when the material cause is the same, either in number (it is a case of the same thing called in different ways) or by species (it is a case of two objects made of the same kind of stuff). There is formal identity when the formal cause is the same. This happens in two ways: if the form at issue is the singular form of the individual composite, then there is a unique object known in different ways; if the form at issue is the common essence instantiated by the singular form, then there are two distinct objects belonging to the same species or genus (*In Metaph*., book V, tr. 2, chap. 3, fol. 185ra). Correspondingly, the main types of distinction (or difference) are also two: material and formal. There is material distinction when the material cause is different, so that the objects at issue are separable entities. In general, there is formal distinction when the formal cause is different. This happens in two ways: if the material cause is also different, then it is a particular case of material distinction. If the material cause is the same, then a further analysis is necessary. If the material cause is the same by species only, then it is an improper case of formal distinction; but if the

material cause is the same in number, then there is properly formal distinction, since the forms at issue have different definite descriptions but share the same substrate of existence, so that they are one and the same thing in reality. For example, there is a proper formal distinction in the case of the two properties of being-capable-of-laughing (*risibile*) and of being-capable-of-learning (*disciplinabile*), which are connected forms instantiated by the same set of individual substances (*In Metaph*., book V, tr. 2, chap. 3, fol. 185rb).

Material distinction is a necessary and sufficient criterion for real difference, traditionally conceived, whereas there is formal distinction if and only if there is one substance in number (i.e. material identity in the strict sense) and a multiplicity of formal principles with different descriptions instantiated by it. Paul therefore inverts the terms of the question in relation to what earlier approaches had done. By means of the formal distinction Duns Scotus and John Wyclif had tried to explain how it is possible to distinguish many different real aspects internal to the same individual substance (the passage is from one to many). On the contrary, Paul is attempting to reduce multiplicity to unity (the passage is from many to one). What Paul wants to account for is the way in which many different entities of a certain kind (i.e. of an incomplete and dependent mode of existence) can constitute one and the same substance in number.

2.2 Predication

The starting point of Paul's theory of predication is his doctrine of universals. Just like Wyclif and his followers (Alyngton, Penbygull, Sharpe, Milverley, Whelpdale, Tarteys), the Augustinian master claims that

1. There are real universals, which are common essences naturally apt to be present in and predicated of many similar individuals.
2. Real universals and their individuals are really the same and only formally distinct.
3. Predication is first of all a real relation between metaphysical entities (*QdU*, fols. 124ra, 124vb, 127va, 132va).

But his analysis of predication is different from those of both Wyclif and his followers. In fact, Paul divides predication into identical predication and formal predication and defines them in a different way than his sources do.

To speak of *identical predication* it is sufficient that the form signified by the subject-term of a (true) proposition and the form signified by the predicate-term share at least one of their substrates of existence. This is the case for propositions like ‘Man is (an) animal’ and ‘The universal-man is something white’ (‘*Homo in communi est album*’). One speaks of *formal predication* in two cases:

1. When for the truth of the proposition it is necessary that the form signified by the predicate-term is present in *all* the substrates of existence of the form signified by the subject-term, in virtue of a formal principle (made clear in the proposition itself) that is in turn directly present in all the substrates of existence of the form signified by the subject-term. This is the case for propositions

like ‘Man is formally (an) animal’ and ‘Socrates *qua* man is an animal’.
2. Or else when the predicate of the proposition is a term of second intention, like ‘species’ or ‘genus’. This is the case for propositions like ‘Man is a species’ and ‘Animal is a genus’ (*SN*, part VI, chap. 2, fol. 93vab; *QdU*, fols. 124vb-125rb).

As is evident, identical predication is extensionally defined, whereas formal predication is intensionally defined, since formal predication entails a relation modally determined between the subject-thing and the predicate-thing. In fact, formal predication presupposes that there is a *necessary* connection between the subject-thing and the predicate-thing of the given proposition. For this reason, Paul denies that sentences like ‘(What is) singular is (what is) universal’ (‘*Singulare est universale*’), which Wyclif and his followers acknowledged as true, are in fact true propositions. For Wyclif and his followers, the sentence at issue is an example of predication by essence. But for Paul of Venice, it is an example of formal predication; no individual *qua* individual is an universal, or *vice versa*, as no second intention intensionally considered is any other second intention (*QdU*, fol. 133va; *In Porph*., *prooem*., fol. 3ra-b). As a consequence, Paul rewrites the preceding sentece in this form: ‘(What is) singular is *this* universal’ (‘*Singulare est hoc universale*’), where the presence of the demonstrative ‘this’ changes the kind of predication from formal to identical. So corrected, the sentence is true, since it signifies that a certain entity, in itself singular, is the substrate of existence of a universal essence (*QdU*, fol. 133va-b).

As a result, Paul builds up a mixed system, where the copula of the standard philosophical sentences he deals with can have a threefold value: it means a partial identity between the subject-thing and the predicate-thing in the case of identical predication; it means a necessary link between forms in the case of the first type of formal predication; it means that the subject-thing in virtue of itself is necessarily a member of a given class of objects, which the predicate-term of the proposition labels and refers to, in the case of the second type of formal predication -- that is, when the predicate is a term of second intention.

3. Ontology

Paul's world consists of finite beings (that is, things like men or horses) really existing outside the mind, each made up of a primary substance and a host of forms existing in it and by it. The forms of a primary substance belong to ten different types of being, or categories. Therefore a finite being cannot be totally identified with the primary substance. (In fact no primary substance contains the whole being of a finite being.) Rather it is an ordered congeries of categorial items. Primary substances are not simple items but complex objects, since they are compounded of particular matter and form -- a form that is really identical with and formally distinct from the specific nature itself that the primary substance instantiates (*SN*, part VI, chap. 1, fols. 92vb-93ra). The concepts of matter and form are relative, since their meanings are connected with each other (*In Post*., fol. 40rb). Being the form of something and being the matter of something are converse relations of three different kinds, whose arguments and values are:

1. the metaphysical constituents of the individual substance (i.e. singular matter and form);
2. the metaphysical constituents of the specific natures (i.e. genus and difference); and
3. the categorial items (i.e. individual and universal substances and accidents) considered according

to their various degrees of generality.

The specific nature (or essence) can be conceived from a twofold point of view: intensionally (*in abstracto*) and extensionally (*in concreto*). Intensionally viewed, the specific nature simply expresses the set of essential properties that compose a categorial form, without any reference to the existence of individuals which, if there are any, instantiate it. Extensionally viewed, the specific nature is that same form conceived of as instantiated by at least one singular entity. For instance, human nature intensionally considered is humanity (*humanitas*); extensionally it is man (*homo*) (*In Porph*., *prooem*., fol. 9va). Both of them are substantial forms superordinated to the whole human compound, but while humanity is properly a form, i.e. something existentially incomplete and dependent, man is an existentially autonomous and independent entity. Thus they differ from each other in the same way as a predicate (for example ‘*P*’) differs from a formula (for example, ‘*P*(*x*)’).

Because of the complexity of the metaphysical composition of the finite corporeal being, every creature has four different levels of being: real, essential, temporal, and individual. The real being is nothing but the whole reality of the finite being. The essential being is the mode of being proper to the specific nature that a certain singular directly instantiates. The temporal being is the state of affairs designated by infinitival expressions like ‘being a man’ (‘*hominem esse*’) or ‘being white’ (‘*esse album*’) -- that is, the object of the act of judging. Finally, the individual being is the actual existence of the primary substance of a finite being as distinct from the whole reality of the finite being itself (*SN*, part VI, chap. 1, fol. 92vb).

According to Paul, who follows Duns Scotus and Wyclif on this subject, being is univocally shared by everything real, since it is the stuff that the ten categories modulate according to their own essence (*In Phys*., book I, tr. 1, chap. 2, t. c. 13; *In Metaph*., book IV, tr. 1, chap. 1, fols. 122ra-125vb, *passim*; *In Porph*., chap. *De specie*, fol. 22rb). In view of this position, Paul maintains no real distinction between essence and being (*In Metaph*., book IV, tr. 1, chap. 2, fol. 127rb; book VI, chap. 1, fol. 223vb). Like Duns Scotus and Wyclif, Paul speaks of a formal difference (or difference of reason) between essence and being in creatures, as the essence and the essential being of a thing are one and the same entity considered from two distinct point of view, intensionally (the essence) and extensionally (the being) (*SN*, part VI, chap. 1, fol. 93ra).

This analysis identifies the opposition between essence and being with the opposition between universals and individuals. Like Wyclif, Paul thinks of the essence as a universal form intensionally considered, and the existence (taken in the strict sense) as the mode of being proper to primary substances. Thus, when Paul affirms that essence and being are really identical and formally different, he simply restates the thesis of the real identity and formal distinction between universals and individuals that was typical of the Realists of the late Middle Ages. Consequently, like Burley and Wyclif, Paul holds that a formal universal actually (*in actu*) exists outside our minds only if there is at least one individual that instantiates it, so that without individuals common natures (or essences) are not really universals (*SN*, part VI, chap. 2, fol. 94ra).

This means that the relationship between common natures and singulars is ultimately grounded on

individuation, since no actual universality and no instantiation is possible without individuation. On this subject Paul successfully reconciles the Scotistic approach with certain Thomistic theses. Paul claims that the principle of individuation is twofold, immanent and remote. The immanent principle is the one whose presence necessarily entails the existence of the individual it constitutes, and whose absence necessarily entails the non-existence (or disappearance) of the individual. The remote principle, on the other hand, is just what the immanent principle presupposes, but whose presence and absence alone are insufficient for causing the existence or disappearance of the individual, as it continues being after the corruption of the individual. Thisness (*haecceitas*) is the immanent principle of individuation, whereas form, matter, and quantity are the remote principle. Thisness in turn has a twofold origin, as it derives from matter and form together in the case of corporeal substances, and as it derives from the essence (*quidditas*) alone in the case of angelic intelligences (*SN*, part VI, chap. 5, fol. 95vb). Furthermore, according to Paul there is a close similarity between the thisness, which he now calls individual difference (*differentia individualis*), and the specific difference. The specific difference is what differentiates the species from the genus, since it is the determination or property which, once added to the genus, results in the species. On the other hand, the specific difference is really identical with the genus, from which it is distinct only in virtue of a formal principle. The same happens to the individual difference: it is what differentiates the individual from the species; from the ontological point of view, it is really identical with and formally distinct from the species itself; and it is the formal principle in virtue of which the individual is what it is, something particular, concrete, and perfectly determined in itself (*SN*, part VI, chap. 5, fol. 96rb; chap. 26, fol. 112rb-va; *QdU*, fol. 128va; fol. 129rb; *In Metaph*., book III, tr. 1, chap. 1, fol. 83vb).

As far as the problem of angelic individuation is concerned, the logical consequence deriving from such premisses is that it is impossible to find two angels who share the same specific nature and are numerically distinct, since only one *haecceitas* can spring up from an incorporeal species (*SN*, part VI, chap. 5, fol. 96ra). This solution is close to the inner meaning of Duns Scotus' position and contrasts with Aquinas' view, although Paul affirms that the angelic intelligences are specifically, and not numerically, different. In fact, according to St. Thomas, angels are specifically different because they are incorporeal, and without matter no individuation is possible. On the contrary, Paul of Venice thinks angels are individuated by means of thisnesses, but not multiplied by them, because of the absence of matter, so that there is only one angel per species. Since specific natures of incorporeal beings do not include any reference to matter, only a unique principle of individuation (*ratio suppositalis*) can flow from such species. As a consequence, no angel is one in number in the strict sense of the term (as being one in number necessarily implies the actual presence of a multiplicity of things of the same species), even though broadly speaking every angel is one in number, as two (or more) angels are, after all, "many things" -- but never many angels of the same kind (*SN*, part VI, chap. 5, fol. 95vb).

In his last work, the commentary on the *Ars Vetus*, Paul summarizes his position as follows:

1. The individual is the final result of a process of individuation whose starting point is a specific form.
2. The individuation is what differentiates the individual from its species.
3. The individuation is nothing but the thisness itself.
4. The thisness and the specific form are only formally distinct from the individual they make up (*In*

Porph., chap. *De specie*, fol. 60ra).

5. The principle of individuation, when causing the passage from the level of universals to that of singulars, does not play the role of form (or act) in relation to the specific nature, but the role of matter (or potency), as it is what the specific form structures (*In Cat*., chap. *De substantia*, fol. 60ra).

In this way Paul of Venice tried to solve the aporetic aspects of Duns Scotus' theory of individuation. Scotus said nothing about the problem of the relation between the thisness and the particular matter and form that constitute the individual. The Franciscan master was silent also about a possible identification of the thisness with one of the two essential forms of the individual substance, the *forma partis* (for instance, the individual soul) and the *forma totius* (the human nature). Paul identifies the principle of individuation with the informing act through which the specific nature molds its matter. This identification had been already suggested by the opposition between immanent and remote principles of individuation described in the *Summa philosphiae naturalis*. In fact, all the constituents of the individual compound (matter, form, and quantity) had been contrasted with the thisness, which for that reason could not be identified with any of them. Moreover, it is obvious that:

1. It is the union of the singular form with its matter that establishes the "birth" of the individual.
2. It is its separation from the matter that establishes the "death" of the individual.
3. The union of the singular form with its matter is the necessary and sufficient condition for the passage of the specific essence from its abstract (or intensional) mode of being to its concrete (or extensional) mode of being.

4. Psychology

Paul of Venice rejects the Augustinian conception of the relation of soul to body and follows the Aristotelian view of the soul as form of the body. But, against Aristotle and following Aquinas, Paul claims that, although it is the form of the body, the human soul is a self-subsistent form, and therefore incorruptible. However, unlike St. Thomas, he claims that the human soul is twofold, since the complete human soul derives from the close union of two distinct principles, the cogitative and the intellective ones. The former is the cause of the animality and the latter of the rationality of man; neither of them can exist in man without the other, and the cogitative soul is in potency in relation to the intellective soul (*SN*, part V, chap. 5, fol. 69ra; *In De anima*, book II, t. c. 23, fol. 48ra).

Like St. Thomas and Giles of Rome, Paul maintains that there is a real distinction between the soul and its faculties. But, in opposition to them, he holds that there is only a formal distinction (*ratione et definitione*) between the faculties themselves (*SN*, part VI, chap. 4, fol. 68ra-b). Whereas the faculties of the cogitative soul depend on bodily organs for their operations, the faculties of the intellective soul, i.e. the active intellect, the passive intellect, and the will, are independent of bodily organs, even though in the state of union with the body they need sensation for exercising their powers and no act of sensation can be produced without the concurrence of the body (*SN*, part V, chap. 10, fols. 71va-72ra). Besides the vegetative faculty (which regulates nutrition, growth, and reproduction) and the power of locomotion, the

faculties of the cogitative soul are the following: the five exterior senses, the general sense (*sensus communis*), the fantasy (*phantasia*), the power of assessment (*vis aestimativa*), and memory. Against Avicenna, Paul explicitly denies that there is a fifth internal sense, the imagination, since he thinks its presumed operations are the same as those of the fantasy (*SN*, part V, chap. 30, fol. 84ra). The general sense distinguishes and collates the data of the special exterior senses. The fantasy conserves sensible species apprehended by senses and freely combines them together to produce figments. The power of assessment recognizes those properties of things which cannot be perceived through the senses, like, for example, that something is useful for a certain purpose, or friendly, or unfriendly. The memory is the ‘warehouse’ where all the sensible species are stored, so that the cogitative soul can perform its tasks even without the presence of any sensible object (*SN*, part V, chap. 30, fol. 84ra-va).

According to Nardi 1958, Ruello 1980, and Kuksewicz 1983, Paul was an Averroist in Psychology, as he would have supported the thesis of the unicity and separate character of the passive intellect for the whole human species. But this is false. On the contrary, Paul's point of view is close to that of St. Thomas for the question of the passive intellect, and to the position of Avicenna for the question of the active intellect (Conti 1992, especially pp. 338-47). If his affirmations in the *Summa philosophiae naturalis* are ambiguous and it is therefore possible to miss their deepest meaning, in his commentaries on the *De anima* and on the *Metaphysics* he clearly rejects all the main theses of the Averroism. First of all, he maintains personal immortality (a thesis denied by genuine Averroists) and, like the medieval followers of Avicenna, identifies active intellect with God's activity of ‘illumination’ in the soul (*In De anima*, book III, t. c. 11, fol. 137rb; t. c. 19, fol. 143ra). Secondly, he claims, against Averroes, that the intellective soul is form and act of the body (*In De anima*, book II, t. c. 7, fol. 39rb-va; t. c. 8, fol. 134rb). Moreover, he asserts that:

1. The intentional species present in the exterior senses, in the internal senses, and in the intellect are of three different kinds.
2. The individual is a proper object of intellection for us.
3. The same intelligible species (*species intelligibilis*) by means of which we grasp substantial essences is the medium in virtue of which we can understand the peculiar structure of the individual which instantiates that essence. (*SN*, part V, chap. 28, fol. 83ra; *In De anima*, book III, t. c. 11, fol. 136vb; 137rb-va).

These theses are just the opposite of Averroist convictions. Finally, he explicitly argues against the unicity of the passive intellect, utilizing some arguments drawn from the *De unitate intellectus contra Averroistas* (*On the Unicity of Intellect against the Averroists*) and the *Summa theologiae* (*Summa of Theology*) of St. Thomas. Among them, the most important are the following three:

1. If the soul is the form of the body, as Aristotle states, it is impossible that the passive intellect is one in all men, since one and the same principle in number cannot be the form of a multiplicity of substances.
2. If the passive intellect is one and the same for all men, then after death nothing remains of men but this unique intellect, and in this way the bestowal of rewards and punishments is done away with.
3. One and the same intellect could hold contradictory opinions at once, in apparent violation of the

law of contradiction (*In De anima*, book III, t. c. 27, fol. 149ra; *In Metaph*., book IV, tr. 1, chap. 3, fols. 136vb-137ra).

More generally, he thinks (i) the Averroistic theses are lacking in a solid philosophical basis, since they can be maintained from the physical point of view only, according to which everything is considered *qua* affected by or connected with motion, but (ii) they are totally false from the metaphysical point of view, which is the most comprehensive of all. From this viewpoint, according to which the passive intellect has to be considered a substantial form, it is evident that it has a beginning in time, but certainly not an end, and that, like any other material substantial form, it is multiplied according to the multiplication of bodies (*In Metaph*., book XII, tr. 1, chap. 3, fol. 427ra-b).

Marsilius of Inghen

Marsilius of Inghen, master at the Universities of Paris (1362-1378) and Heidelberg (1386-1396), wrote a number of treatises on logic and natural philosophy popular at many late medieval and early modern universities. He adopted the logico-semantic approach of William of Ockham and John Buridan while at the same time defending the traditional views of Thomas Aquinas and Bonaventure. His thinking sheds light on the discussion between nominalists and realists and allows insight into the changing interests of philosophy and theology, from the critical attitude of many fourteenth-century authors to the search for tradition which was characteristic of the fifteenth century.

---

1. Life and Works

Marsilius of Inghen was born around 1340 in Nijmegen, a city in the eastern part of the Low Countries (Netherlands). In the older literature it is often said that he came from one of the villages in the vicinity of Nijmegen (Inghen), but this view is mistaken. It was based on a confused reading of the *Oratio Funebris* held in 1396 by Nicholas Prowin at the funeral of Marsilius and published in 1499 at Mainz. From 1362 on, Marsilius was master at the Faculty of Arts at the University of Paris, where he was also rector (1367 and 1371), and a student of theology. As a teacher at Paris, Marsilius was much esteemed and his lectures drew large audiences. Among his students were many compatriots, some of whom came from Nijmegen and surrounding villages. In 1378, Marsilius found himself the University's delegate at the court of Pope Urban VI in Tivoli. In 1379, he instructed one of his colleagues, Hugh of Hervort, to look after his

interests in Paris. After 1379, Marsilius's name is no longer mentioned in the acts of the University of Paris. He probably turned away from Paris because of the imbroglio surrounding the Great Schism of 1378. Meanwhile, he kept in touch with his native city. In 1382 the town council of Nijmegen treated him to a banquet. From 1386 on, Marsilius was master at the University of Heidelberg. There, as in Paris, he held a number of administrative offices. He was one of the founders of the University of Heidelberg, of which he was rector no fewer than nine times, from 1386-1392 and also in 1396. In 1389-1390, as the University's *nuncio* together with Conrad of Soltau, he was responsible for transferring the University register to Rome (Boniface IX). At the beginning of the 1390s, Marsilius again took up the study of theology. The masters who taught theology were by then Conrad of Soltau (since 1387) and Matthew of Krakow (since 1394), both from the University of Prague. In 1395/1396 Marsilius finished his lectures on the *Sentences* and so became the first theologian to obtain the doctorate at Heidelberg. He died a short time later, on August 20, 1396.

Marsilius was a prolific writer. His work was the fruit of his teachings in Paris and Heidelberg. Many of his writings have been preserved in manuscripts or early printed editions, although recently some have appeared in modern critical editions. His most important writings include:

Works on Logic and Epistemology

1. *Exposition of the Old Logic*
2. Various *Questions* on the Old and New Logic
3. *Summary* [Abbreviationes] *of the Old and New Logic*
4. Treatises on the Properties of Terms: *On Supposition, Ampliation, Appellation, Restriction, Obligation, Insolubles, and Consequences*.

Works on Natural Philosophy and Metaphysics

1. *Summary* [Abbreviationes] *of Aristotle's 'Physics'*
2. *Questions on Aristotle's 'On Generation and Corruption'*
3. *Questions on Aristotle's 'De anima'*
4. *Questions on Aristotle's 'Metaphysics'*

Works on Theology

- *Questions on the 'Sentences' of Peter Lombard*

2. Teachings

2.1 Logic and Epistemology

In his logic and epistemology, Marsilius followed the nominalist tradition of the fourteenth century as

exemplified by William of Ockham and John Buridan. Yet Marsilius never qualified himself as a nominalist or follower of Ockham. He was an independent thinker who sometimes went back to the older tradition of the thirteenth century (e.g., in Peter of Spain), or advocated theories which were more in line with ordinary speech, as against the highly specialized views of his contemporaries.

Marsilius's nominalism comes to the fore in his views on the object of scientific knowledge, the nature of universals, and the logical doctrine of supposition. His basic assumption is that there are only individuals and no universals outside the human mind.

2.1.1 The Object of Scientific Knowledge

According to the Aristotelian standard accepted by Marsilius, the object of scientific knowledge must be universal and necessarily true. This is not the case with individual things in the external world, since they are subject to change. Only the conclusion of a true and necessary syllogism can meet the standard. Hence, for Marsilius, the object of scientific knowledge is not anything outside the mind, but the mental proposition which refers to individual things and their qualities. More specifically, the proper object of scientific knowledge is a proposition in the form of a conclusion that has been deduced from necessary premises.

2.1.2 Universals

Marsilius argued that universal concepts such as 'humanity' do not refer to real universals outside the human mind. Accordingly, there is no universal essence in singular individuals. Individuals of one genus or species do resemble each other, however, and this resemblance is the foundation of universal concepts in the human mind. The generation of universal concepts is a natural process, which Marsilius described as follows: suppose individual A of species S evokes concept X in the human mind. This concept is similar to concept Y which has been evoked by B of the same species S. By abstracting from all the differences between X and Y, the human mind is able to produce another concept, Z, which stands for both A and B. Universality is then taken to be a quality of concept Z, the product of the epistemological operation of abstraction on concepts X and Y by the human mind.

2.1.3 Supposition

In line with his account of the nature of universals, Marsilius rejected simple supposition. Logicians such as Peter of Spain had used the notion to indicate that a term stood not for an individual but for a universal or common nature in the external world, like the term 'man' in the proposition, 'Man is a species'. Since Marsilius rejected the idea of universals existing outside the mind, he eliminated simple supposition from the list of different types of supposition. He was critical of some of his contemporaries (e.g., Albert of Saxony) who likewise dismissed the concept of real universals, yet kept on using the notion of simple supposition. They had changed the meaning of the term, he said, by claiming that a written or spoken term had simple supposition if it was used to refer to a concept in the human mind. Marsilius wondered whether young students would be able to understand this new meaning of simple supposition, since they

would hardly know what concepts are. To avoid confusion, Marsilius decided not to deal with simple supposition at all in his logic.

2.1.4 Some Specific Views

Marsilius was his own person when it came to assessing the views of others. In his analysis of the proposition ‘Socrates is not a chimera’ he followed what he called ‘the Parisian method’, according to which the proposition is false because the term ‘chimera’ supposits for nothing, there being no real chimeras to which it can refer. Others, however, considered the proposition to be true.

Elsewhere, he departed from the opinions of the Parisian School (*scola Parisiensis*) and opted for the perspective of ordinary language or common way of speaking (*communis modus loquendi*). This was the case with his analysis of the proposition ‘The Antichrist is not, but he will be’. According to the Parisian School, the term ‘he’ refers to the thing referred to by the term ‘Antichrist’. Since there is no Antichrist, neither term has reference. But in ordinary language it is different, for there the term ‘he’ is meant to refer to the future Antichrist. Marsilius accepted the latter analysis as sound, despite the authority of the former.

Finally, in the definition of ampliation, Marsilius went back to logicians of the thirteenth century such as Peter of Spain, who had defined ampliation as an extension of supposition, whereas fourteenth-century logicians such as Albert of Saxony did not consider ampliation to be a kind of supposition. Marsilius reinterpreted their definition so that it fit better with the older tradition. Such efforts to harmonize older and newer positions were typical of the late fourteenth century.

2.2 Natural Philosophy and Metaphysics

In natural philosophy and metaphysics Marsilius was an empiricist, meaning that he thought all scientific knowledge must be based on either sense data or self-evident propositions, i.e., propositions in which the meaning of the predicate is included in the subject. Everyone who knows the meaning of the terms of such propositions judges them to be evidently true. This has far-reaching consequences for the relationship between philosophy and theology. Since the philosopher uses only sense data and self-evident propositions, his inquiry may come to different conclusion than that of the theologian, who has additional knowledge from scripture. The philosopher makes judgments about the world from a limited human perspective, whereas the theologian is helped by divine revelation. Yet Marsilius took the task of the philosopher seriously because he thought the human mind has a natural tendency to search for truth, which is satisfied (although not ultimately satisfied) in natural philosophy and metaphysics.

2.2.1 Creation

According to the principles of natural philosophy, creation from nothing is impossible. The senses show that things always come from other things. Because there is no serious reason to doubt the information given by the senses, the human mind legitimately jumps to the universal principle that nothing can come

from nothing, driven by the natural tendency to search for truth. Consequently, for the human mind creation from nothing is impossible. It contradicts the universal principle that nothing comes from nothing. That God has created the world from nothing is therefore only a matter of faith (*sola fide est creditum*). Revelation shows that human knowledge of creation is limited, but it cannot be aided by natural philosophy at this point.

2.2.2 Theory of the Human Soul

In the later Middle Ages the study of the soul was part of natural philosophy. Marsilius treated the human soul in his commentary on Aristotle's *De anima*, in which he followed the Parisian tradition of Buridan and Oresme concerning the particular questions addressed. Following Buridan, he argued that there is no natural proof of the immortality of the human soul. For the human natural mind, unaided by revelation, the theory of Alexander of Aphrodisias that the human soul is corruptible is the most probable. That Alexander of Aphrodisias is mistaken and that the soul continues to exist after the death of the body is known through revelation alone. Faith has more authority than human reason and must be accepted in all cases where the two conflict since the things we believe on faith come from God, who cannot err.

2.3 Metaphysics

Although metaphysics cannot surpass the limits of human knowledge, Marsilius considered it to be the entry point to theology. Natural reason is capable of forming some adequate and true concepts of God, but also of forming true propositions about God. It is able to prove that God exists and possesses knowledge and will. But it cannot demonstrate that God has free will or infinite power. This, Marsilius claimed, was also true for philosophers such as Aristotle, whose teachings equal those of natural reason itself.

From Buridan, Marsilius took the idea that God according to Aristotle and Averroes is not only the final cause of the heavens and separate substances, but also their efficient cause. On this point Buridan and Marsilius were following the view of Scotus and Ockham against that of John of Jandun, Johannes Baconis, and Gregory of Rimini. It is worth noting in this connection that in the *Puncta super libros Metaphysicae* (i.e., brief abstracts of Aristotle's *Metaphysics* for teaching purposes) attributed to Johannes de Slupcza and written in Krakow in 1433, some of the views that Marsilius adopted from Buridan, including the one just mentioned, are attributed to Marsilius instead of Buridan -- notwithstanding the fact that the author was familiar with both Marsilius's and Buridan's commentaries. This illustrates the strong influence Marsilius's work exerted on fifteenth-century students and commentators.

2.4 Theology

Marsilius expressed his theological views in a voluminous commentary on the *Sentences*. He quoted and often adopted views that were put forward by fourteenth-century theologians such as Adam Wodeham and Gregory of Rimini, but was also influenced by earlier thinkers such as Thomas Aquinas and

Bonaventure. He has serious reservations about the use of logic in theology.

2.4.1 Attributes and ideas

In his discussion of the divine attributes he followed mainly the teachings of Adam Wodeham. God is perfectly one. Divine wisdom and all other perfections attributed to God are in reality as identical to the divine essence as the divine essence is identical to itself. In the divine essence itself there is no distinction or non-identity whatsoever between the attributes of God. Any distinctions between divine attributes are necessarily of a rational (rather than real) nature and are made by us.

A similarly radical stance on the unity of God was assumed in his treatment of divine ideas. Ideas are not formally distinct in God, as some Scotists would argue, but only extrinsically and objectively distinct. Their distinction is a consequence of the differences between the creatures produced by God (which is why Marsilius spoke of extrinsic distinction), and of the fact that they are known by God as different (which accounts for their objective distinction). God knows that he is the cause of infinitely many differences between creatures. That is why his mind contains infinitely many different ideas.

Marsilius criticized Ockham's view that God's idea coincides with creation. If this were true, Marsilius argued, the idea of producing a stone must be identical with either the stone itself, or the stone insofar as it is known by God. If the former, then God must look outside of himself in his idea, which contradicts the position of Augustine, who is quoted by Ockham. If the latter, then the idea of its production is not the stone itself, but rather God's foreknowledge of the stone.

2.4.2 Theology and logic

Marsilius advanced his criticism of the use of logic in theology in his discussion of the position of Robert Holcot. Holcot had argued that logically, God can be called the cause of evil. If God is the cause of every thing (*entitas*) and moral evil (*malum culpae*) is a thing, then God is the cause of evil. Marsilius acknowledged that the argument is based on true premises, yet the conclusion should not be defended as true because it contradicts faith and therefore might cause confusion among believers. Theologians should not flaunt their personal skills in logic, but always write out of reverence for the divine. Their writings should not erode the beliefs of ordinary people, who are not skilled in logic, but rather aim to strengthen them spiritually.

Marsilius was anxious, however, to avoid the implication that God's foreknowledge is somehow dependent upon human beings. In his discussion of Adam Wodeham on the causality of the human will, he complained that Adam had not been emphatic enough on this point, since he allowed the following argument: if an event *E* will happen in the future, then God knows *E* from eternity; but if not-*E* will happen, then God knows not-*E* form eternity; since man is free, he can choose between *E* and not-*E*; therefore, he can change God's foreknowledge. This argument is logically sound, Marsilius argued, but it easily leads to the false conclusion that God's knowledge depends on the free will of man, which is absurd. The eternal cannot fall under the power of that which is created by it. Therefore, this argument

should not be used. It is better to remain on the safe side by maintaining what has always been maintained, namely that God through his absolute omniscience knows the future activities of human beings, but without being dependent on them.

2.4.3 The sacraments

In his treatment of the sacraments at the end of his commentary on the *Sentences*, Marsilius drew heavily on the writings of Thomas Aquinas and Bonaventure. He defended Thomas's view that the word 'this' pronounced by Christ at the Last Supper in uttering 'This is my body' (Mk. 14:22) refers to what the bread and body have in common. Thomas of Strasbourg had attacked this view, but Marsilius showed that the earlier Thomas was right and the later wrong.

In his discussion of the causality of the sacraments, Marsilius followed the exposition of Bonaventure, according to whom the sacraments have no causality of their own. It is God who acts whenever the sacraments are administered correctly. Only in a broad sense is it true to say that the sacraments have the power to act.

3. Influence

The influence of Marsilius has been considerable, particularly through his logical works and commentaries on Aristotle. This may be gathered not only from the large number of manuscripts that have been preserved, but also from several other considerations. Marsilius's commentary on Aristotle's *Prior analytics* was used in Prague in the 1380s. His logical works, including the *Obligationes* and the *Consequentiae,* were used as textbooks in Vienna in the 1390s. His commentaries on Aristotle's *Metaphysics* and *Physics* were read in Krakow during the first sixty years of the fifteenth century. At the universities of Heidelberg, Erfurt, Basle, and Freiburg, his works were studied throughout the fifteenth century, in particular as part of the university curriculum. In 1499, the doctors and masters of the *Via Moderna* at the University of Heidelberg published a volume that included epigrams on Marsilius by well-known humanists such as Jacob Wimpfeling, as well as a defense of Nominalism in the style of Marsilius (*Via Marsiliana*). Praise in the form of epigrams can also be found in the 1501 Strasbourg edition of Marsilius's commentary on the *Sentences*. The *Obligationes*, printed in 1489 under the name of Peter of Ailly, were used by Thomas Bricot, John Major, and Domingo de Soto. The commentary on the *Prior Analytics* was quoted by Agostino Nifo. Jodocus Trutvetter and Bartholomew of Usingen, who consolidated nominalism in Erfurt, repeatedly mentioned Marsilius in their works. Both Leonardo da Vinci and Galileo Galilei referred to Marsilius's commentary on *De Generatione et Corruptione*.

The theological views of Marsilius appear to have had some circulation as well. His commentary on the *Sentences* was known in Krakow in the first half of the fifteenth century, and was used by Thomas de Strampino in his *Principia* (1441-1442). The University of Salamanca had a theological chair (Cátedra de Nominales) for commentary on the works of Marsilius of Inghen and Gabriel Biel. His commentary on the *Sentences* was quoted by Spanish theologians such as Francisco de Vitoria, Domingo de Soto, Luis de Molina, and Francisco Suárez, usually in connection with questions about divine foreknowledge and

grace.

There are nine extant manuscripts of Marsilius's commentary on the *Sentences*. Among the former owners of these manuscripts were two libraries for preachers (Ansbach and Isny), and two libraries of faculties of arts (Erfurt and Leipzig). The education in Erfurt and Leipzig included the reading of nominalist authors. In all probability, the artists became interested in Marsilius's theological work after studying his writings on logic and physics. The presence of Marsilius's commentary on the *Sentences* in preachers' libraries bears witness to the fact that the impact of his work was felt beyond university circles.

Gregory of Rimini

Gregory of Rimini may have been the last great scholastic theologian of the Middle Ages. He was the first thinker to incorporate substantially the developments of both the post-Ockham tradition at Oxford and the post-Auriol tradition at Paris, and his original synthesis had a long-lasting impact on European thought.

1. Life and Work

Gregory of Rimini (a.k.a. de Arimino, Ariminensis, the "Torturer of Infants," and the *doctor acutus* or *authenticus*) was born in Rimini around 1300. He joined the mendicant Order of the Hermits of Saint Augustine (OESA), studied theology at Paris from about 1323 to 1329, and then taught at various Augustinian *studia* in Italy, first at Bologna, then, after 1338, at Padua and Perugia. Almost certainly while he was in Italy, Gregory came into contact with the works of Oxford scholars from the 1320s and 1330s, most notably William of Ockham, Adam Wodeham, Richard Fitzralph, and Walter Chatton. Gregory returned to Paris in 1342 for a year of preparation for his lectures on the *Sentences*, which were given in 1343-44. Gregory probably became Master of Theology in 1345, but he continued to revise his written commentary until 1346, removing certain passages that until recently were considered later *additiones*. In 1347 he returned to Italy to teach in Padua where he stayed until 1351. After that, he taught at the recently established *studium* in Rimini until 1357, when he was elected the Augustinians' prior general, succeeding the late Thomas of Strasbourg. Gregory died in Vienna toward the end of 1358 (see V. Marcolino's chapter in Oberman 1981, 127-94).

Gregory's most important writing by far is his commentary on the first two books of the *Sentences*. Book I survives in some twenty complete manuscripts, while there are about a dozen for book II. The work was printed several times from 1482 to 1532, reprinted in 1955, and finally received a modern critical edition in six volumes in 1979-84 (Rimini 1979-84; Bermon 2001). Parts have been or are being translated into French, German, and English (Rimini, forthcoming). In addition to scriptural commentaries and his letters as prior general, smaller works have also been attributed to Gregory, including a work on usury, *De usura*, printed in Reggio Emilia in 1508 and in Rimini in 1622, and a treatise on the four cardinal virtues, *De quatuor virtutibus cardinalibus*. His tract on the intension and remission of forms, *De intensione et remissione formarum corporalium*, carries the incipit "Circa secundum partem huius distinctionis" and is, therefore, just an excerpt of the *Sentences* commentary, book I, distinction 17, part 2.

2. Position in the History of Philosophy

Although Gregory of Rimini has received considerable attention from historians of medieval thought, understanding his position in the history of philosophy has been made difficult by several problems that have plagued the historiography of fourteenth-century scholasticism. He flourished at a time that has been judged by historians as on the whole decadent, fideistic, and radically skeptical, in contrast to the period in which, for example, Thomas Aquinas worked (d. 1274); this historical viewpoint already made difficult an objective evaluation of Rimini. Historians also labeled Gregory a "nominalist," a term so broad and vague when applied to fourteenth-century thinkers that, when it was used without qualification, it tended to mislead and to obscure the differences among them, as for example between Ockham and Gregory. Finally, unlike Aquinas, Henry of Ghent, and John Duns Scotus, Gregory was active in an as yet severely understudied period, so that placing Gregory in his context is difficult and statements about Gregory's originality are precarious. The history of Gregory's own University of Paris in the quarter century before his *Sentences* lectures, in contrast to that of Oxford in the same years, is particularly unclear. Only careful diachronic studies of specific philosophical problems can provide a precise picture of Gregory's role in the history of philosophy, and few such studies have been accomplished thus far. There are some, however, and epistemology, foreknowledge, and predestination are examples of topics about which we know quite a bit (see below).

Generally, what has been learned so far is that Gregory was really the first to introduce to the University of Paris the exciting ideas developed at English schools between William of Ockham (ca. 1319) and Thomas Bradwardine (ca. 1344). Beginning with Gregory the names of Adam Wodeham, Richard Fitzralph, Walter Chatton, William Heytesbury, Thomas Buckingham, Richard Kilvington, Robert Halifax and others became common knowledge among Parisian scholars. Gregory was also deeply influenced by recent thinkers at his own university, both negatively and positively. The impact of Peter Auriol has long been recognized to be great, but recent studies have made clear that other figures, such as Francis of Marchia, Thomas of Strasbourg, Gerard Odonis, and Michael of Massa, had an influence on Gregory. The question of Gregory's relationship to his Parisian predecessors needs to be investigated more fully.

More clear is Gregory's importance in the late Middle Ages and Reformation. Many scholastics after 1350 copied large passages from his works. Prominent figures who plagiarized or borrowed from Gregory include the Cistercian James of Eltville, Pierre d'Ailly, and Henry of Langenstein, but other important thinkers such as Hugolino of Orvieto OESA, Marsilius of Inghen, and Peter of Candia OFM (Pope Alexander V) knew Gregory's works well. Few philosophers in the later fourteenth century can have been unaffected by his ideas. Gregory's impact both inside and outside the Augustinian Order continued into the fifteenth century. In the celebrated quarrel over future contingents at the University of Louvain (1465-1474), for example, several of the participants cited Gregory's position or even adopted it without attribution. Of course, the fact that only books I and II of Gregory's commentary circulated means that Gregory's direct impact is to be found in topics discussed in those books rather than in issues covered in books III and IV, such as the Immaculate Conception and the Eucharist, which had their own philosophical sub-issues.

Perhaps the most central element of Gregory of Rimini's thought and influence is his adherence to Augustine and the nature of that adherence. For one thing, Gregory simply read Augustine more carefully and extensively than most previous thinkers, and so, for example, Gregory was able to attack Peter Auriol for his faulty citations and quotations of Augustine. Gregory's interest in the works of Augustine has been seen as central to the development of a "historico-critical" method in philosophical theology, especially in the Augustinian Order, partly foreshadowing modern scholarly methods. In connection with this historico-critical method, Gregory was part of a general attempt to establish reliable texts of Augustine and to separate authentic works from the pseudo-Augustinian corpus. Quotations from Augustine, moreover, were cited with great accuracy and detail in Gregory's writings, and so his *Sentences* commentary, when not plagiarized for his own ideas, was often used as a source for Augustinian quotations (Trapp 1956).

Not surprisingly, Gregory's ideas are often Augustinian. Gregory's brand of doctrinal Augustinianism, influenced rather by the Franciscan and Oxonian tradition than the more Dominican (and Parisian) variety of Giles of Rome, soon dominated the Augustinian Hermits' philosophy and theology. Thus by the early 16th century *Aegidistae* and *Gregoriistae* schools of thought existed, and a recognized *via Gregorii* was present in many universities such as Wittenberg, the university of Gregory's fellow Augustinian Hermit Martin Luther (McGrath 1987). The fact that each book of his *Sentences* commentary was printed six times between 1482 and 1532 further helps explain why some of Gregory's ideas often resemble those of Luther and Jean Calvin. Gregory's thought may even have had a life after the reformation in Francisco Suarez.

A list of Gregory's philosophical positions would perhaps not be difficult to make, and neither would it be hard to describe his relation to Ockham on various topics (e.g. Smith 1999). In natural philosophy, for example, in agreement with Ockham, Gregory was a nominalist and employed "Ockham's" razor in denying that sudden change, motion, and time, for example, are independent entities (Brown 1998b). Gregory also claims that the world could have been eternal, and that an actual infinite is possible (Maier 1949). But in these cases one would like to know better the stances of Gregory's immediate predecessors, especially Parisians like Francis of Marchia, in order to determine the possible sources and degree of originality of Gregory's ideas. Otherwise, a list of Gregory's ideas is just that, a mere list. Consequently

the focus here shall be on issues on which the theories of Gregory and his predecessors have been investigated in some depth.

3. Foreknowledge and Contingency

In many ways Gregory was a philosopher's theologian, because he began with propositions from Scripture as premises for his arguments and proceeded deductively. In his deductive theology, Gregory devoted much time and space to defining his terms and exploring exhaustively the implications of possible solutions, a practice that makes his *Sentences* commentary a joy to read and a philosophical classic. In distinctions 38-41 of book I, Gregory tackled the general problem of divine foreknowledge and future contingents and the specific dilemma of predestination and free will. Gregory's positions on these questions have already been the subject of study for many decades, and recently historians have attempted to put Gregory into his immediate Parisian and Oxonian context. Moreover, Gregory's nickname, "the Torturer of Infants," stems in part from his stance on predestination. A discussion of Gregory's thought on these issues, therefore, provides a convenient introduction both to his noetic and to his position in history.

Gregory's treatment of divine foreknowledge and future contingents is aimed primarily at Peter Auriol and secondarily at Oxford theologians (Vignaux 1934, ch. 4; Hoenen 1993, 196-214; Schabel 2000, 264-274; Rimini, forthcoming). In order to preserve the contingency of events stemming from human free will, Auriol claimed that propositions about future contingents are neither true nor false, but rather neutral, and so God does not know that the Antichrist will exist, since "the Antichrist will exist" is neither true nor false. Although like Ockham and Rimini later, Auriol maintained that exactly how God knows the future is incomprehensible to us, he did give a sophisticated explanation and defense of God's knowledge of our future. Gregory, however, chose to focus on the above-mentioned elements in Auriol's position. Gregory recognized that Auriol's theory of future-contingent propositions relies on Aristotle's stance in chapter 9 of *On Interpretation*. Interestingly, although Gregory denied the truth of the position itself, he nevertheless held that it was in fact Aristotle's. Indeed he rejected any attempt to interpret Aristotle differently, in the way that many medieval and modern philosophers have tried to do:

> [This] is apparently a friendly excuse, but in truth it is more of an accusation, because the fact that absurdities ensue [from this position] does not convince us that [Aristotle] did not think that, but convinces us that he ought not to have thought that... Moreover, some modern theologians [i.e. Auriol], great teachers, said that the conclusion [denying determinate truth to future-contingent propositions] not only was the Philosopher's intention, but also that it is very true and even demonstrated... (Rimini 1979, 243).

So for Gregory, Auriol was correct that Aristotle denied the Principle of Bivalence when applied to propositions about future contingents.

Auriol set up two basic rules for such propositions: (1) if a proposition about the future, say, "Socrates will run," is true, it is true immutably and inevitably, since no instant can be found when it would be

false. (2) The significate of such a proposition will inevitably and necessarily be put into being. The foundation for Auriol's claim is his modal theory: immutability and necessity are the same thing. If something is immutable, it cannot be different from what it is, and so it necessarily is the way it is.

Gregory answered with a rigorous and lengthy defense of Bivalence and an alternative modal theory. His defense of Bivalence includes a detailed set of rules for propositions. It is significant that this section of Gregory's text, some seven pages, stems from Francis of Marchia's refutation of Auriol's position, a refutation adopted and extended by Gregory's own Augustinian predecessor at Paris, Michael of Massa. In short, Gregory argued that the Principle of Bivalence applies universally, and Aristotle was wrong to make an exception in the case of future-contingent propositions. Although this was his basic disagreement with Auriol, Gregory was so careful a philosopher that before he refuted Auriol on this point he corrected his Franciscan predecessor on details and in so doing made Auriol's own theory more precise.

Auriol placed greater emphasis on divine simplicity and necessity than on divine freedom and contingency when he was wrestling with one of the fundamental problems of Christian philosophical theology: given an absolutely simple and necessary God, what is the source of contingency? Auriol's own explanation lies in God's relationship with events in time, but this explanation was not of interest to Rimini, who was convinced by Scriptural prophecy that God does in fact know the future, and convinced by logic that the Principle of Bivalence holds universally. So the problem becomes, if God knows that Socrates will run, and the proposition "Socrates will run" is true, will not Socrates run necessarily?

Rimini's answer is a version of the *opinio communis*, a position with roots in Scotus and the Parisian tradition but which Ockham and later Oxford scholars refined with their focus on propositions. (It is possible that Ockham was influenced by Auriol in his concentration on future-contingent propositions, as some have held, but there is nothing specific to indicate that Ockham knew Auriol's treatment, and after Scotus it was natural for theologians to focus their attention on the truth of future-contingent propositions anyway.) The *opinio communis* relies on God's freedom to save contingency in the world: everything other than God is ultimately contingent, because God wills and acts freely and contingently in creating, and so it is logically possible for the things in the world not to have been or to have been otherwise. At the same time, the common position affirms God's immutability and determinate knowledge of such things. The upshot is that true propositions about future contingents have always been true and are immutably true, even determinately true, but that they are only contingently true and not necessarily so. So Gregory denies Auriol's equation of necessity and immutability.

Gregory's position relies on interesting uses of common logical devices and distinctions developed at Paris and Oxford over the preceding century, such as the distinction between the composite and divided senses of propositions, and that between conditional and absolute necessity. The purpose of these distinctions was to offer a way of explaining the contingency of events, but in doing so they assumed the ultimate contingency of everything except God. However, far from being an affirmation of the "radical contingency" of the world, as some historians have claimed, it was in fact the only way for most theologians to save at least some contingency from the threat of absolute logical and divine determinism. In fact, Gregory and others admitted that, assuming God's knowledge of the future, the future was

necessary *ex suppositione*, although not absolutely, because it is logically possible for immutable God to know otherwise. Peter Auriol, and later Peter de Rivo, Pietro Pomponazzi, and Martin Luther, would consider these efforts feeble and deluded. The three Peters resorted to alternative theories that others considered equally feeble and deluded, whereas Luther simply accepted the conclusion that all attempts to save meaningful contingency governed by human free will were doomed to failure.

What is interesting about Gregory's treatment, again, is not his originality, but the clarity and precision with which he presented the common position. He even pointed out problems in the discussions of those with whom he broadly agreed, such as Ockham. True, almost all of what Rimini said could be found in Marchia, Massa, Ockham, Landulph Caracciolo, Adam Wodeham, and others, but not in such an organized fashion.

One final element of Gregory's stance on modal matters that deserves our attention is the contingency or necessity of the past. The *opinio communis* maintained that the past is somehow necessary in a strong sense, even though it is not absolutely necessary. It seems that Gregory did not go so far as to say that the past is necessary (beyond the normal necessity *ex suppositione*), but he does make some sort of modal distinction between the past and the future. Thus we can say that Gregory did not think God can change the past, although there has been some disagreement on this issue (Courtenay 1972-73; Schabel 2000, 271-2). Suffice it to say that the time has come for a long and careful treatment of the modal status of the past in medieval thought, to determine whether any thinker ever really thought the past could be changed. The probable answer is negative.

4. Predestination

Predestination was the traditional subject of distinctions 40-41 of commentaries on book I of the *Sentences*. This was a more purely "theological" subset of the more "philosophical" topic of foreknowledge and future contingents treated in dd. 38-39. As in the case of foreknowledge, Gregory proceeded slowly and carefully, defining his terms and outlining the possible positions. Gregory's Augustinian bent shows through more clearly in predestination than in foreknowledge. Gregory quoted Augustine's words no less than 43 times, and cited him still more often. Frequent scriptural quotations, carefully chosen, provide the ultimate basis for his theory. From Romans 9.13, where Paul comments on Malachi 1.2, "Jacob I have loved, but Esau I have hated," Gregory took his position that from eternity, God actively elects to damn some and to save others, a theory called Double Predestination or Double Particular Election (Vignaux 1934, ch. 4; Schüler 1934; Halverson 1998, 143-157; Schabel 2001; Rimini, forthcoming).

The main issue is what the causal connection is between humans' willing and acting and their salvation or damnation, and predestination or reprobation: do humans participate in or contribute to their own salvation and damnation, or is God's will the sole cause? Traditionally the answer had been that humans are the cause of their deserved damnation, but that salvation depended solely on God's will. Although there were various interpretations of this traditional stance, Peter Auriol seems to have been the first important university scholar to provide a real alternative. Auriol had already sought to distance God from

the everyday details of the world's existence, in order to preserve divine necessity and the contingency of things. Auriol now applied his general theory to the specific issue of soteriology, and claimed that God sets up general rules by which certain sets of people will be damned and other sets saved, without actively choosing to save or damn specific individuals. This maintained divine immutability but had the added bonus of providing symmetry for reprobation and predestination: the determining factor is the presence or absence of an obstacle to grace (*obex gratiae*). For Auriol, while someone's obstacle to grace is indeed a positive cause of reprobation, the absence of such an obstacle, however, is merely a *negative* or privative cause of predestination. Thus Auriol thought he could avoid charges of Pelagianism by simply denying a *positive* cause of predestination in the elect. Ockham appears to have adopted the main elements of Auriol's stance, while Walter Chatton at Oxford and Gerard Odonis and Thomas of Strasbourg at Paris went further and posited a positive cause of predestination in the elect, which would appear to approach the condemned Pelagian doctrine.

Gregory reacted by charging that both the theory of the privative cause and the notion of the positive cause of predestination in those who are predestined are Pelagian. Instead Gregory returned to the traditional view as it concerned predestination: it stems only from God's merciful will. However, Auriol's criticism of the asymmetry of the traditional position led Gregory to claim that not only do the predestined play no causal role in their salvation, but neither do the reprobate contribute to their damnation. In short, there is no reason either for one person's salvation or for another person's damnation except the inscrutable will of God: we do not know why some are saved and others damned. This, after all, Gregory believed, was the theory of Paul and of Augustine.

One has to admire Gregory's consistency here, mirroring that of his opponent, Peter Auriol. In the case of divine foreknowledge, Auriol provided an alternative to the traditional position because he claimed that the common defense of contingency failed. Auriol's theory allowed him to preserve the causal role of humans in reprobation, at the expense perhaps of involving humans in predestination and therefore coming close to Pelagianism. There were problems with Auriol's stance, but it was consistent. Gregory, on the other hand, agreed with the common position on divine foreknowledge, but when it really counted, in soteriology, Gregory took this common position to what he (and Auriol) thought was its logical conclusion. Since God's free creation and action is really the only source of contingency in the world, then God's free will is the only real cause of salvation and damnation. Salvation and damnation are contingent like anything else, but not contingent upon human free will, but merely on God's will. No doubt for Gregory, everyone else who held the *opinio communis* should also have held to Double Predestination or Double Particular Election. Luther and Calvin agreed with Gregory, but they saw no reason for the logical devices of the *opinio communis*, which for them as for Auriol could not save the contingency of human willing.

5. Cognition

Epistemology is another subject in which Gregory's thought has received much attention (e.g. Elie 1937; Dal Pra 1956; Gál 1977; Eckermann 1978; V. Wendland's chapter in Oberman 1981, 242-300; Tachau 1988, 358-71). As in natural philosophy, Gregory maintains a non-realist position that universals are

formed by the soul and only after the mind has previous apprehensions of singular things. Thus sensory experience plays a major role in intellectual cognition. For simple cognition Gregory adopts the common terminology of the dichotomy between intuitive and abstractive cognition, although the difference between the two is based on the objects rather than the modes of cognition. For Gregory, intuitive cognition terminates immediately at the extramental object, but abstractive terminates at the object's species in the soul. Inspired by some of Ockham's successors, Gregory argues against the Venerable Inceptor's claim that via intuitive cognition one could determine whether a thing does *not* exist.

In agreement with Auriol against most contemporaries, however, Gregory also holds that one can have an intuitive cognition of an object that does not exist, as for example when we see a "broken" pencil in a glass of water, when there is only an unbroken pencil in reality. But Auriol is wrong in claiming that this is an instance of an intuitive cognition of something absent, because for Gregory the cognition is really caused by the species of some present object, although perhaps not the object that the mind thinks it is. Therefore Gregory does not adopt Auriol's definition of intuitive cognition as the cognition when the soul merely thinks that the object is present. In any case the dichotomy is different for Gregory because he maintains that abstractive cognition is also somewhat intuitive, since the species of the object is known immediately and therefore intuitively.

In the course of Gregory's long discussion of the problem of foreknowledge and future contingents, he makes frequent reference to the notion of the *complexe significabile*. When it comes to complex cognition, or scientific knowledge, Gregory's inspiration was Adam Wodeham, who built on some of Walter Chatton's ideas in developing the *complexe significabile*. Ockham held that the object of scientific knowledge is the conclusion of a syllogism, and Gregory rejects this. Chatton's alternative was that scientific knowledge has as its object things outside the mind. Gregory also denies this, because

> if this were the case, many sciences would be about contingent things that could be different than they are, whereas for strict science the object must be eternal and necessary. Every being, however, besides God is contingent and not necessary. If things outside the mind were the objects of the sciences, then many sciences, physical and geometrical, and many others, would be about things other than God, and therefore about contingent things (Rimini 1979, 6; Brown 1998a, 171).

One can see here how Gregory's stress on the overarching contingency of creation connects with his epistemology.

Gregory chooses as the object of scientific knowledge the alternative offered by Adam Wodeham. Chatton's notion of "thing" in scientific knowledge was the state of affairs signified by both the negative and the affirmative proposition. For example, "Socrates is sitting" and "Socrates is not sitting" signify for Chatton the same thing, not Socrates, not sitting, and not the propositions, but somehow the whole Socrates's-being-seated. Although Chatton had his reasons for his theory, Wodeham modified it in a useful way, differentiating between positive and negative states of affairs. Thus for Wodeham, each proposition has its own total significate that is only complexly signifiable (*complexe significabile*), so

that Socrates's-being-seated and Socrates's-not-being-seated are two different things, the objects of scientific knowledge.

Gregory adopted Wodeham's theory and tailored it where necessary to his own thought. The complexe significabile, once thought to be Gregory's invention, is neither the proposition itself (although it determines the truth or falsity of the proposition) nor individual things in the world, but rather the arrangement of things in the world. He differed from Wodeham, for example, in the way he thought about "assenting to" and "dissenting from" such *complexe significabilia*, an issue which had occupied Chatton at length. Gregory then applied the notion to a host of other philosophical problems, such as future contingents, and through him the *complexe significabile* became the common intellectual property of continental thinkers, and parallel notions are found in many important later intellectuals.

Now that Gregory's works are available in a reliable modern edition, it is to be hoped that further studies of his Parisian and Oxford predecessors on various single issues will enable us to see his innovations more clearly. Recent studies have shown that he was not always as original as was once thought, but that does not diminish in any way his important position in the history of philosophy. Moreover, Gregory sometimes did come up with new solutions to problems, and even where he did not, his treatments, because of their clarity and comprehensiveness, often became the primary source for later thinkers of the ideas he adopted from his predecessors and developed.

William Penbygull

Wyclif's logico-metaphysical works were very influential at Oxford at the end of the 14th century and the beginning of the 15th. Among the authors who followed his doctrines (the so called Oxford Realists), William Penbygull (+1420) was almost certainly the most faithful to the master, since his extant writings appear to be essentially devoted to a defence and/or explanation of Wyclif's main philosophical theses. Notwithstanding such an attitude, Penbygull gave an original contribution to logic by developing a new theory of identity, which solved the problems that Wyclif's analysis of predication had raised, and by refining Wyclif's theory of predication itself.

Life and Works

The information on the life and works of William Penbygull (or Penbegyll) is scanty. He was from Exeter diocese; he studied at Oxford, where he was fellow of Exeter College in 1399, and rector in 1406-07. He was licensed to preach in the diocese of Bath and Wells on 28 February 1410. He probably died at Oxford in 1420. According to Emden 1957-59, he wrote the following treateses on logic: *De universalibus* (*On Universals*), *Divisio entis* (*The Division of Being*), and *Super Porphyrii Isagogen* (*On Porphyry's Isagoge*).

Universals and Predication

Like Wyclif and many other Realists of the late Middle Ages, Penbygull lists three main kinds of universals: (i) the metaphysical causes of everything, like God and the angelic intelligences; (ii) the general concepts abstracted by our mind, or mental universals; and (iii) the common natures existing in the singulars, or real universals (*De universalibus*, p. 178). Such common natures are type-forms

naturally apt to be present-in and predicated-of a set of individuals, which therefore instantiate them. Real universals are the main metaphysical components of the individuals, but they have no being outside the being of their individuals, as universals and their individuals are really (*realiter*) the same and only formally (*formaliter*) distinct (*De universalibus*, p. 189). In fact, real universals are identical with their own individuals when considered as natures of a certain kind (for instance, man is the same thing as Socrates), but different from them when considered *qua* universals and *qua* individuals respectively, because of the opposite constitutive principles: generality for universals and thisness for individuals (*De universalibus*, p. 181).

Like Walter Burley and Wyclif, Penbygull holds that such formal universals exist in act (*in actu*) outside our minds, and not in potency (*in potentia*) only, as moderate realists (like St. Thomas) thought, since for Pengygull the necessary and sufficient condition that a thing must meet for being a universal is the existence of at least one individual in which it is present (*De universalibus*, p. 178). So the actual existence of universals depends entirely on that of their individuals; without them, common natures could not be really universals.

On the logical side, this description of the relationship between universals and individuals in terms of real identity and formal distinction, entails that not all that is predicated of individuals can be *directly* (*formaliter*) attributed to their universals and *vice versa*. In particular, the accidental forms inhering in substantial individuals (for instance, the whiteness inhering in Socrates) can be predicated of the universal forms proper to these individuals (for instance, the form of humanity or that of animality) only *indirectly* (*essentialiter*), through and in virtue of the individuals themselves. As a consequence, a redefinition of the standard kinds predication and the introduction of a new type, unknown to Aristotle, was required, in order to cover the cases of indirect inherence of an accidental form in a substantial universal, admitted by this theory.

Wyclif, whose conception of universals is the source of Penbygull's, had therefore distinguished three main types of predication: formal predication, predication by essence, and habitudinal predication, each more general than the preceding one. Since the ontological presuppositions of the most general type of predication (habitudinal predication), implied by the other types, are completely different from those of the other two, Penbygull, like other Oxford logicians of his generation, tried to improve Wyclif’ theory by excluding habitudinal predication and redefining the other two kinds in a slightly different way. Penbygull therefore divides predication (which he conceives as a real relation which holds between metaphysical objects [*De universalibus*, p. 188]) into formal predication (*praedicatio formalis*) and predication by essence (*secundum essentiam*). Predication by essence shows a partial identity between subject and predicate, which share some, but not all, metaphysical component parts, and does not require that the form connotated by the predicate-term be directly present in the essence denotated by the subject-term. Formal predication, on the contrary, requires such a direct presence. If the form connotated by the predicate-term is intrinsic to the nature of the subject, then the predication is a case of formal essential predication, while if it is extrinsic, the predication is a case of formal accidental predication. "Man is an animal" is an instance of formal essential predication; "Socrates is white" is an instance of formal accidental predication. Unlike Wyclif, who applied predication by essence to second intentions only -- since he admitted sentences like "(What is) universal is (what is) singular" (that is, *universale est*

singulare) as well-formed and true -- Penbygull thinks that it holds also when applied to first intentions. So he claims that it is possible to predicate of the universal-man (*homo in communi*) the property of being white, if at least one of its individuals is white. However he makes sure to use as a predicate-term a substantival adjective in its neuter form, because only in this way can it appear that the form connoted by the predicate-term is not directly present in the subject, but is indirectly attributed to it, through its individuals. Therefore he acknowledges the proposition "The universal-man is (something) white" (*homo in communi est album*) as a true one, if at least one of the existing men is white (*De universalibus*, pp. 186-88). According to him formal essential predication and formal accidental predication would correspond to Aristotle's essential and accidental predication. But, as a matter of fact, he agrees with Wyclif in regarding predication by essence as more general than formal predication. As a consequence, in his theory formal predication is a particular type of predication by essence. This means that he implicitly recognizes a single ontological pattern, founded on a sort of partial identity, as the basis of every kind of standard philosophical statement (subject, copula, predicate). But in this way, formal essential predication and formal accidental predication are very different from their Aristotelian models, as they express degrees of identity as well as predication by essence.

The Theory of Identity

This interpretative scheme of the nature and kinds of predication is ultimately grounded on a notion of identity, necessarily different from the standard one. According to the most common opinion the logical criteria for identity and (real) distinction were the following:

> *a* is identical with *b* iff for all *x*, it is the case that *x* is predicated of *a* iff it is predicated of *b*;
>
> *a* differs from (is [really] distinct from) *b* iff there is at least one *z* such that *a* is predicated of *z* and *b* is not, or *vice versa*, or there is at least one *w* such that *w* is predicated of *a* and not of *b*, or *vice versa*.

On this basis one can easily conclude that universals and individuals can never be the same, at least because of the forms of generality (which cannot be predicated of individuals) and of thisness (which cannot be predicated of universals). So Penbygull had to put forward new criteria for identity and distinction. First of all, he distinguishes between the notion of non-identity and that of difference (or distinction) and denies that the notion of difference implies that of non-identity (*De universalibus*, p. 190); then he affirms that the two notions of difference and (real) identity are logically compatible (*ibid.*); finally he suggests the following definitions for these three notions non-identity, difference or distinction, and (absolute) identity (*De universalibus*, pp. 190-91):

> *a* is non-identical with *b* iff there is not any form *F* such that *F* is present in the same way in *a* and *b*;
>
> *a* differs from *b* iff there is at least one form *F* such that *F* is *directly* present in *a* but not in

b or vice versa;

a is (absolutely) identical with *b* iff for all forms *F*, it is the case that *F* is present in *a* iff it is present *in the same way* in *b*.

The criterion for non-identity is stronger than the common one for real distinction: two things can be qualified as non-identical iff they belong to distinct categories. On the other side, the definition of difference does not exclude the possibility that two things which differ from each other share one or more properties (or forms). Thus, there are degrees of distinction, and what is more, the degree of distinction between two things can be read as the inverse measure of their (partial) identity. For instance, if we compare the list of the forms (both substantial and accidental) which constitute Socrates and those which make up the universal-man, it is evident that Socrates and the universal-man differ from each other, since there are forms which directly inhere in Socrates and not in the universal-man and *vice versa*; but it is also evident that the two lists are identical for a long section, that is, that Socrates and the universal-man, considered from the point of view of their metaphysical composition, are partially the same. As a result, the copula of the propositions which Penbygull deals with cannot be extensionally interpreted, as it does not mean that a given object is a member of a certain set, nor that a given set is included in another, but it always means degrees in identity between two compound entities.

Johannes Sharpe

Johannes Sharpe (ca. 1360 - after 1415) is the most important and original author among the so called `Oxford Realists', a group of thinkers influenced by John Wyclif's logic and ontology. His semantic and metaphysical theories are the final output of the main preceding traditions of thought, since he developed the new form of realism started up by Wyclif, on the one hand, but was open to many Nominalistic criticisms of the traditional Realistic strategies, on the other.

---

1. Life and Works

Johannes Sharpe (Scharp, Scharpe) was from the diocese of Münster in Westphalia, where he was born presumably around 1360. He received his Bachelor of Arts from the University of Prague in 1379, but spent the greatest part of his academic life in Oxford, where he was fellow at Queen's College from 1391 to 1403, and where he became a Master of Arts and a Doctor of Theology. In 1415 he was *lector ordinarius* in Lüneburg (Saxony) (see Conti 1990, p. xvii). The date of his death is unknown.

He established a reputation as a philosopher and a theologian. The number of extant manuscripts of his works and their widespread distribution attest to his importance and notoriety throughout the 15th century. The following writings are attributed to him:

- a treatise on universals (*Quaestio super universalia* [*QsU*] -- his only edited work);
- a commentary by questions on Aristotle's *On the Soul* (*Quaestio super libros De anima* [*In De anima*] -- 8 mss.; all references are to the ms. Oxford, New College 238);
- a commentary by questions on Aristotle's *On Physics* (*Quaestio super libros Physicorum* -- 7

mss.);

- a treatise on the properties of being (*De passionibus entis* -- 3 mss.);
- a treatise on formalities (*De formalitatibus* -- one ms. only);
- an abbreviation of Duns Scotus' *Quodlibeta* (6 mss.);
- a group of six short treatises on theological subjects (one ms. only).

2. The Theory of Meaning

The basic idea of the standard Medieval Realist theories of meaning was that semantic classifications derive from ontological differences among the signified objects. So, according to this approach, the simple expressions of our language (i.e. names) are distinct from the complex expressions (i.e. sentences) by virtue of their own *significata*, that is by virtue of the different kinds of objects they refer to. In fact, the objects signified by complex expressions are compounds of (at least) two of the objects signified by simple expressions and a relation of identity (or non-identity, in the case of a true negative sentence), while a simple object is an item in a category (i.e. either a singular substance, or a substantial form, or an accidental form). Furthermore, every simple expression of our language is like a label that names just *one* object in the world, but whereas proper names and singular expressions label individuals (i.e. token-objects), general terms label common natures (i.e. type-objects), which are the main metaphysical constituents of the set of individuals that instantiate them. For instance, the general expression `man' labels and can stand for each and every man only because of its primarily signifying the universal form of manhood *qua* being present in each and every man as the main constitutive principle of his essence.

Sharpe rejects the standard Realist criteria for the generality (or universality, according to his terminology) of terms, and substantially accepts the inner sense of Nominalist criticisms. In his opinion, to be matched by a common nature really existing in the world is no longer the necessary and sufficient condition for being a general term. According to him, signifying universally (that is, signifying a unitary concept that in turn refers to a multiplicity of things displaying at least a similar mode of being [*QsU*, pp. 129-30]) is a condition for semantic universality equally as important as the previous one. He thinks that not only do terms that signify a common nature existing outside the intellect have to be viewed as common, but also those that signify universally (*ibid.*, p. 69). Thus according to Sharpe there are six different kinds of general expressions, both spoken and written:

1. those that universally singify a common nature really existing in the world (*in re*), like the term `manhood';
2. those that universally connote a common nature really existing in the world, without directly signifying it, like the term `white' (`*album*'), which refers to white things and connotes the form of whiteness;
3. those that do not refer to anything really existing in the world, but are somehow correlated with a universal concept, like the terms `void' and `chimaera';
4. those to which no common nature really existing in the world corresponds, but rather a common transcategorial negative concept, under which a multiplicity of things can be collected, like the term `individual';

5. equivocal terms as such, since they are connected with a multiplicity of different notions;
6. demonstrative pronouns, like `this (one)', when used to supposit for (refer to) a common nature, even though they can signify only in a singular manner (*discrete*) (*ibid.*, pp. 69-71).

The fourth kind of general terms deserves particular attention, since it is connected with Sharpe's solution to the question of the semantic and ontological status of terms of second intentions like `individual' or `singular' -- a question that was very controversial in Oxford at the end of the 14th century. The most common explanation was that proposed by Robert Alyngton, a fellow of Queen's College in the 1380s. According to Alyngton, terms like `individual' have to be considered singular expressions; more precisely they are "range-narrowed" expressions, like `this man', because they identify a singular referent as a member of a given (manifested) set of individuals. In fact, a term like `individual' presupposes a general concept (that of being), the range of which is narrowed to just a unique object among beings by an act of our intellect -- to one object that is not common. Sharpe argues that Alyngton's answer goes against linguistic usage as well as established facts. If Alyngton were right, then the following argument (which everybody will admit) would be formally incorrect:

> man runs (*homo currit*)
> and not the universal-man (*et non homo communis*)
> therefore an individual man runs (*ergo homo singularis currit*),

just like this other one:

> man runs (*homo currit*)
> and not the universal-man (*et non homo communis*)
> therefore Socrates runs (*ergo Sortes currit*),

since the syntagm `an individual man' (`*homo singularis*') would be a singular term standing precisely for only one individual, just like `Socrates' (`*Sortes*'). Furthermore, it is a fact that anyone can understand the sentence `an individual man runs' even without knowing who the man who is running is -- which is, on the contrary, a necessary requisite according to Alyngton's theory. Therefore, Sharpe regarded second intentions of this kind as common ones (*ibid.*, pp. 132-33).

In this way, Sharpe admits that the Nominalist explanation of the universality of signs holds in the particular context of second intentions, implicitly rejecting Alyngton's reduction of epistemology to ontology, since according to Sharpe's account the former has its own range and rules partially independent of those of the latter. Furthermore, he restores the semantic rank that intuitively would be assigned to the `individual'-like terms (something Alyngton was unable to do). On the other hand, his defence of Realism on the problem of universals is partially invalidated by the acceptance, although restricted, of the Nominalist principle of the autonomy of thought in relation to the world. In fact, it is evident that from a semantic and/or epistemological point of view he can no longer justify the extra-mental reality of universals.

Like Burley's system, Sharpe's semantic system too lists a third kind of expression between simple and complex expressions: concrete accidental terms (like `white' or `father'), whose *significata* are neither simple nor complex objects but something in between. He affirms that concrete accidental terms do not signify simple objects but aggregates composed of a substance and an accidental form. Such aggregates are lacking in numerical unity, and hence do not fall into any of the ten categories, because they are not properly beings (*entia*). For that reason concrete accidental terms, although simple expressions from a merely grammatical point of view, are not names. The two metaphysical components of such aggregates (i.e. substance and accidental form) are related to the concrete accidental term as follows: although the concrete accidental term connotes the accidental form, this latter is not its direct *significatum*, so that the concrete accidental term can supposit for the substance only. In other words, the concrete accidental terms label substances by means of the accidental forms from which they draw their names, so that they name substances only *qua* bearers (*subiecta*) of a form. This fact accounts for the difference between general names in the category of substance (like `man') and concrete accidental terms. General names in the category of substance are concrete terms as well, but the form they primarily signify is really identical with the substances they label. Therefore, in this case, the name itself of the form can be used as a name of the substance. This obviously implies a slight difference in meaning between abstract and concrete substantial terms, like `manhood' and `man'. While `manhood' is not the name of the form considered in its totality, but rather the name only of the essential principle of the form, that is, of the intensional content carried by the term `man', this latter term signifies the substantial form considered as a constitutive element of the reality (*esse*) of a certain set of individual substances that instantiate it. As a consequence, according to Sharpe, `man is manhood' (`*homo est humanitas*') is a well formed and true sentence, since both subject and predicate signify the same entity, but `white is whiteness' (`*album est albedo*') is not, since `white' does not directly signify the accidental form, but only the substrate in which it inheres, as bearer of that form, and therefore `white' cannot stand for such a form in any sentence (*ibid.*, pp. 71-73).

3. Universals and Predication

The core of Sharpe's metaphysics lies in his theory of universals. He is a Realist, since he defends the extra-mental existence of universals (*ibid.*, p. 68), but his approach to the whole matter can be defined as "analytical," since he seems to believe that (i) any ontology has to be built up in relation to the resolution of semantic problems, (ii) any philosophical explanation of reality has to be preceded by a semantic explanation of the function of our language, and (iii) that there is not a close correspondence between elements and structures of language and elements and structures of the world. So Sharpe distinguishes two main kinds of universals: universal forms, like manhood, really present in a multiplicity of things, and universal signs, both mental and extra-mental, by means of which we refer to real universals and/or signify something in a universal manner (*ibid.*, p. 50; see also p. 68). On the other hand, the theoretical framework of this division is an analysis of the various meanings of the term `universal'. According to Sharpe, they are six, since we can count the following entities universal:

1. causes that have a multiplicity of effects;
2. the ideas in God;

3. the universal quantifier (*syncategorema universaliter distributivum*);
4. universal propositions, both affirmative and negative;
5. universal forms, or real universals; and
6. universal signs (*ibid.*, pp. 49-50).

The being of real universals coincides with the being of their own individuals, so that real universals can be said to be everlasting, because of the continuous succession of their individuals, and really identical with them. On the other side, universals and individuals are formally different from each other, as they have distinct constitutive formal principles, and therefore different properties (*ibid.*, pp. 91-92). The most important among universal signs are mental universals, which are both the acts of intellection through which our mind grasps the nature of universal forms and the concepts through which it connects general names with the things to which they refer (*ibid.*, pp. 68-69). As a consequence, his position on the problem of universals can be summed up as follows:

1. Universals exist in a twofold way, as common natures *in re* and as concepts in our mind.
2. Real universals are naturally apt to be present in many things as their main metaphysical components.
3. Mental universals are partially caused in our mind by the common natures existing outside.
4. Real universals have no being outside the being of their individuals.

Sharpe's theory of universals is obviously modeled on the canons of the moderate Realism. Nevertheless an important difference divides his position from the most common moderate Realist ones (exemplified by Aquinas' doctrine): whereas according to St. Thomas universals exist *in potentia* outside the mind, and *in actu* only in the mind, according to Sharpe's account they exist *in actu* outside the mind, since their being is the same as the being of individuals, which is actual. For Sharpe a universal is *in actu* if and only if there is at least one individual in which it is present. Therefore our mind does not give actuality to universals, but only a separate mode of existence.

The description of the relationship between universals and individuals in terms of real identity and formal distinction entails (i) that not all that is predicated of individuals can be *directly* (*formaliter*) attributed to their universals and *vice versa*, but (ii) that all that is predicated of individuals has to be in some way or another attributed to universals and *vice versa*. Therefore a redefinition of the standard kinds of predication was required. Like Alyngton and Penbygull, Sharpe modifies Wyclif's theory of predication. Thus he divides real predication, which is a real relation between two entities of the world, into formal predication (*praedicatio formalis*) and predication by essence (*praedicatio essentialis vel secundum essentiam*). Predication by essence shows a partial identity between the subject thing and the predicate thing, which share some metaphysical component parts, and does not require (or even excludes) that the form connoted by the predicate term be directly present in the essence signified by the subject term. Formal predication, on the contrary, requires such a direct presence (*ibid.*, pp. 90-91).

Unlike Alyngton and Penbygull, Sharpe does not divide formal predication into formal essential predication and formal accidental predication, and, as is evident from his formulations, offers two

different readings of the distinction between formal predication and predication by essence. According to Alyngton and Penbygull, predication by essence is more general than formal predication; as a consequence, in their theories formal predication is a sub-type of predication by essence. Besides this interpretation, Sharpe admits another one, according to which the two kinds of predication at issue are complementary although not mutually exclusive. This is the case if predication by essence *excludes* that the form connoted by the predicate term be *directly* present in the essence signified by the subject term (*ibid.*, p. 91).

4. Psychology and Theory of Knowledge

The sources of Sharpe's psychological and epistemological theories are St. Thomas, Duns Scotus, and Ockham, altough this latter is chiefly a polemical source, as Kennedy 1969 pointed out (pp. 253 and 270).

Like Aquinas, Sharpe

1. maintains that the intellectual soul is the immediate form of the human body, so that the whole being of the latter totally depends on the former, although souls are individuated by bodies (*In De anima*, fols. 217v-218r), and
2. claims that each man has his own intellect, arguing against Averroes' thesis of the unicity and separate character of the passive intellect for the whole human species (*ibid.*, fols. 210r-212v).

Like Duns Scotus, Sharpe thinks there is not a real distinction between the soul and its intellective faculties (i.e. the active intellect, the passive intellect, and the will) or among the intellective faculties themselves, but only a formal distinction. On the other hand, the soul's corporeal powers (*potentiae incorporatae*), which depend on bodily organs for their operations, are really distinct from the soul and from each other (*ibid.*, fol. 236v). In this context, Sharpe defines two different kinds of formal distinction. According to the first description, which is very close to that proposed by Scotus in his *Ordinatio*,

> two entities *x* and *y* are formally distinct iff (a) both of them are constitutive elements of the same reality, but (b) neither of them can exist by itself, and (c) neither is part of the definite description of the other.

This is the distinction that holds among the intellective faculties of the soul. The second kind of formal distinction holds between the essence of the soul and its intellective faculties and between a species and its individuals. Sharpe draws the definition of this second kind of formal distinction from Wyclif's *Tractatus de universalibus*. It can be formalized as follows:

> two entities *x* and *y* are formally distinct iff (a) there is at least one *z* such that *z* is predicated of *x* and not of *y*, or *vice versa*, but (b) *x* and *y* are really identical, since one is

directly predicated of the other (*ibid.*, fol. 236r-v).

Like Aquinas and Duns Scotus, and against Ockham, Sharpe affirms that intelligible species are required for intellection (*ibid.*, fol. 244r). The main arguments he uses in favor of this thesis are the following:

1. Our mind's objects of intellection are the universal essences or common natures. But they cannot be present themselves to the mind. Therefore some sign of them, that is, the intelligible species, has to be directly present in the intellect.
2. A universal principle of intellection is necessary in order to understand a universal object, like a common nature. The phantasm is particular, since it is the mental representation of a singular object. Therefore a universal species, abstracted from the phantasm, is required.
3. If there were no species, nothing would be retained by the intellect after an act of intellection. Therefore we could not understand each other, or understand more easily the second time, since there would be no objects for our memory (*ibid.*, fols. 239v-240v).

Finally, like Duns Scotus and Ockham, and against St. Thomas, Sharpe states that our intellect can know perfectly even individual material things (*ibid.*, fol. 253r). What is more, it can know immaterial beings as well, since the most general and proper object of our intellect is being in all its amplitude (*ibid.*, fol. 253v). Sharpe here distinguishes perfect knowledge from complete knowledge. For a perfect knowledge of something it is sufficient that our intellect is able to single the object at issue among any other by a proper concept. For a complete knowledge of something it is necessary that our intellect is able to list all the properties, both substantial and accidental, of the object at issue. It is therefore evident that we can have a perfect knowledge of something without completely knowing it, as is the case with individual material things and immaterial beings (*ibid.*, fol. 254r-v).

Sophismata

In contrast to the meaning the word ‘sophism’ had in ancient philosophy, ‘*sophisma*’ in medieval philosophy is a technical term with no pejorative connotation: a *sophisma* is an ambiguous, puzzling or simply difficult sentence that has to be solved. As an important element of scholarly training in universities, closely related to different kinds of disputations, the *sophismata* not only served to illustrate a theory but, from a more theoretical point of view, were also used to test the limits of a theory. The so-called *sophismata*-literature assumed more and more importance during the thirteenth and fourteenth centuries, and it is not an exaggeration to claim that many important developments in philosophy (mainly in logic and natural philosophy) appeared in texts of this kind, where masters could feel free to investigate problems and develop their own views, much more than they could in more academic and strictly codified literary genres.

1. The Word ‘*Sophisma*’

Although some medieval theologians -- and Humanists even more, of course, like Vivès or Rabelais -- used the words ‘sophism’ or ‘sophist’ as a derogatory designation for quibbling philosophers, ‘*sophisma*’ in medieval philosophical literature has a very precise and technical signification. Hence, to avoid any confusion with fallacies and badly-constructed arguments, we shall here use the original term ‘*sophisma*’ rather than the word ‘sophism’ that even nowadays still has a pejorative connotation.

2. Description and Characteristics

2.1 *Sophisma*-Sentences

There are several important characteristics of *sophismata*. First of all, a *sophisma* is a *sentence* rather than an argument. In particular, a *sophisma* is a sentence that either:

1. is *odd* or has odd consequences,
2. is *ambiguous*, and can be true or false according to the interpretation we give it, or
3. has nothing special about it in itself, but becomes *puzzling* when it occurs in a definite context (or "case," *casus*).

Here are some some examples of kind (1), sentences that are odd or have odd consequences:

> This donkey is your father.
> A chimaera is a chimaera.

As examples of kind (2), *ambiguous* sentences that can be true or false according to the interpretation given to to them, consider:

> All the apostles are twelve.
> The infinite are finite.
> Every man is of necessity an animal.

As an example of kind (3), sentences that have nothing special about them in themselves, but that become puzzling when they occur in a definite context ("case," *casus*), consider:

> The sentence ‘Socrates says something false’, in the case where Socrates says nothing other than ‘Socrates says something false’.

(This is paradoxical, and is one of the forms the Liar paradox can take.)

2.2 The Aim of the Discussion

Once the odd, ambiguous or puzzling *sophisma*-sentence is set out, one should try to understand what it means, what implications it has, and how it fits into or contradicts a particular theory under consideration. This is called "solving the *sophisma*," and is the aim of the entire discussion. The way solutions are searched for and established is very similar to the highly formalized scholastic method for determining a "question":

1. First, one has to examine the arguments *pro* and *contra*.
2. Second, one has to present his own solution to the problem. (Sometimes this part of the discussion is preceded by certain theoretical remarks or clarifications that make the terminology more

precise.)
3. Third, one has to refute the arguments supporting the opposite answer.

An Example

Let us take a very simple example, from Albert of Saxony, *Sophismata*, *sophisma* xi. The *sophisma* is:

> *Omnes homines sunt asini vel homines et asini sunt asini.*
> (All men are donkeys or men and donkeys are donkeys.)

In accordance with step (1), here are the *pro* and *contra* arguments:

> Proof: The *sophisma* is a copulative sentence (in modern logical terminology, a conjunction) each part of which is true; therefore the *sophisma* is true, since its analysis becomes: [All men are donkeys or men] and [donkeys are donkeys].
>
> Disproof: The *sophisma* is a disjunctive sentence each part of which is false; therefore the *sophisma* is false, since its analysis becomes: [All men are donkeys] or [men and donkeys are donkeys].

This is a *sophisma* of the second kind above, one that rests on an ambiguity and can be read with a true interpretation or with a false interpretation. Many such *sophismata*, although not this one, resist being translated from Latin into another language without losing the ambiguity. For example, the sentence 'aliquem asinum omnis homo videt' can be translated by 'Every man sees a donkey' as well as by 'There is a donkey that every man sees'. Similarly, in solving *sophismata*, sometimes Latin word-order is used as an arbitrary code for interpreting the sentence. For example, according to William Heytesbury, when the word 'infinite' is placed at the beginning of a sentence and belongs to the subject, it has to be interpreted as a syncategorematic term; in any other case, it is usually interpreted as a categorematic term (Heytesbury, *Sophismata*, *sophisma* xviii, fol.130va). Such word-order codes might seem like reasonable regimentations of language to a Latin-speaker, but in translation they often seem quite implausible and forced. No such problems arise with this example. (For clarity, square brackets have been inserted into the proof and disproof above, in order to indicate the ambiguity of the *sophisma*.)

In accordance with step (2) above, Albert of Saxony, who discusses this *sophisma*, solves it by just saying that it is either true or false depending on which interpretation we choose. He then takes the opportunity to review the basic principles governing the truth-value of copulative and disjunctive sentences.

In accordance with step (3), we would normally be required to refute the opposite answer. In this case, however, there is nothing to refute, since Albert's solution accepts both the *pro* and the *contra* arguments (for different readings of the *sophisma*).

In general, a *sophisma* was a good occasion to discuss all the problems related to a specific issue. For example, the *sophisma* '*Album fuit disputaturum*' ('The white [thing] was going to be disputed') in thirteenth-century Parisian literature was the occasion to discuss all the problems related to the theory of reference in tensed contexts, as well as to refute the positions others held on this very controversial subject. This is why Pinborg 1977 (p. xv) says that at Paris in the thirteenth century "the *sophismata* seems -- within the faculty of arts -- to play a role analoguous to the *Quaestiones quodlibetales* [quodlibetal questions] in the faculty of theology." Note that this use is quite common. (Note also that Pinborg here uses the word '*sophismata*' to signify not only *sophisma*-sentences but the whole literature that discussed them as well.)

Syncategorematic Terms, Exponible Sentences

It is important to recognize that many *sophismata* involve syncategorematic terms that are responsible for their odd, ambiguous or puzzling character. The preceding *sophisma* can be considered quite characteristic of the genre insofar as we see that the syncategorematic terms 'or' and 'and' occur in it and are responsible for the ambiguity of the sentence.

The expression 'syncategorematic term' should be taken in a broad sense here, so that it not only includes classical syncategorematic terms like 'and', 'if', 'every', etc., but also categorematic terms like 'infinite' or 'whole' that can be used both categorematically and syncategorematically. Thus the sentence "*Infinita sunt finita*" ("The infinite are finite" -- here, incidentally is another good example of a *sophisma* that cannot be translated into English without disambiguating it) is false if 'infinite' is used categorematically, for in that case its signification is "Things that are infinite are finite." But it is true if 'infinite' is used syncategorematically, for in that case its signification is "Finite things are infinite in number" or "There are infinitely many finite things." (See Heytesbury, *Sophismata*, *sophisma* xviii, fol.130va.)

Many *sophismata* too are what medieval logicians called "exponible sentences", sentences that seem to be simple but actually imply several other sentences into which they can be decomposed. For example, the sentence "<u>A</u> differs from <u>B</u>" was said to be equivalent to "<u>A</u> exists and <u>B</u> exists and <u>A</u> is not <u>B</u>"; the sentence "<u>A</u> ceases to be white" was said to be equivalent either to "Now <u>A</u> is white and immediately after this <u>A</u> will not be white" or to "Now <u>A</u> is not white and immediately before this <u>A</u> was white", depending on the theory.

2.3 The Main Fields in Which *Sophismata* Are Discussed

Just as the scholastic method can be applied to any subject, the use of *sophismata* is to be found in logic, grammar and physics as well as in theology. Let us concentrate here on the first three.

Logical *Sophismata*

As seen above, logical *sophismata* are closely linked to the discussions of syncategoremata. The aim is

either to determine the truth-value of a sentence (including sentences involving self-reference) or to discuss subjects such as:

- The syntactic and semantic properties of terms (including the difference between meaning and reference) in sentences like "Every man sees every man," "You are a donkey," and "I promise you a horse."
- Quantification and existential import, as in the sentence "Every phoenix is."
- The theory of negation and "infinite" words, as in the sentence "Nothing and a chimaera are brothers."
- The problem of universals, as in "Man is a species."
- The composite and divided senses of a sentence and the scope of modal operators, as in "The white can be black," "Every man is of necessity an animal," etc.

We could compare these discussions to contemporary discussions of sentences like "The morning star is the evening star."

Physical *Sophismata*

The aim here is to discuss physical concepts (motion, change, velocity, intension and remission of forms, maxima and minima, etc.). But, as seen above with the *sophisma* "The infinite are finite," physical problems are treated as logical and conceptual problems. This logico-semantical approach to physical problems is quite characteristic of medieval physics and should be kept in mind when we wonder the extent to which medieval physics can be considered a precursor to modern physics.

With respect to so-called physical *sophismata*, special attention should to be paid to certain fourteenth century English authors known as the "Oxford Calculators," authors like Richard Kilvington, William Heytesbury, Thomas Bradwardine, Richard and Roger Swineshead. These people developed a peculiarly "English-style" of *sophismata.* Based on the theological dogma of the absolute power of God, the distinction between what is physically possible and what is logically possible (where non-contradiction is the only limit) allowed these authors to make use of imaginary thought experiments. For example, "Suppose that A is a distance to be traversed which Socrates cannot traverse, and that his power is increased until Socrates can traverse distance A completely, and that Socrates' power is not increased further." Is the *sophisma* "Socrates will begin to be able to traverse distance A" true or false? (Richard Kilvington, *Sophismata, sophisma* 27, in Kretzmann 1990, p.60.) Thought experiments like these led these authors to, among other things, a theorem for uniformly accelerated motion (Thomas Bradwardine's "Mean Speeed Theorem").

Grammatical *Sophismata*

Sophismata like "Love is a verb," "O Master," "It rueth me" or "I run" gave rise to very sharp discussions of grammatical categories and theories. For example, does a change of word order change the meaning of a proposition? Can a participle be a subject? How should we interpret interjections? Can ‘*est*’ ("is") be

used impersonally?

3. The Various Roles of *Sophismata*

The first and most evident role of *sophismata* is pedagogical. In theoretical treatises, *sophismata* can play various roles. They can be used to explain a given statement or rule, illustrate a distinction or an ambiguity, show what would follow if a rule were violated, or test the limits of a theory.

In addition, although some differences can be identified between the Paris and the Oxford traditions, *sophismata* are important as oral exercises (disputations) in a student's training in philosophy, especially in the first years of universitary education in the Faculty of Arts. Nevertheless, it is clear that, while Heytesbury's *Rules for Solving Sophismata* is written for undergraduate students -- at Oxford '*sophista*' was the official name given to students who had disputed "on *sophismata*" ("*de sophismatibus*") for about two years -- this is probably not the case for his *Sophismata*, the discussions in which are much more complicated.

I think it is no exaggeration to say that *sophismata* in the Faculty of Arts were as important as Biblical exegesis in the Faculty of Theology.

4. Related Kinds of Treatises

If we look at the evolution of literary genres, we note that the twelfth- and early-thirteenth century *syncategoremata*-literature came to be absorbed in the *sophisma*-literature. In thirteenth and fourteenth century philosophical literature, *sophismata* can appear within many kinds of treatises. There are collections of *sophismata* named simply *Sophismata* or *On Sophismata*, but *sophismata* are also important in works -- often by the same authors, or by different authors coming from the same milieu as the former collections -- with titles like *Abstractions*, *Distinctions*, *On Exponibles*, *On Consequences*, *Sophistry*, etc.

Even if there are technical distinctions among these types of tracts, all of them play the same roles mentioned just above -- in short: to acquire logical abilities that can be applied to any subject.

Bibliography

The medieval *sophismata*-literature is a vast and complex subject of research. Many questions are still unsolved, especially about its historical origins and development. It is of central interest for people interested in medieval logic, grammar and physics, but also for those interested in the history of universities.

The study of "sophismatic works" began around 1940 with Grabmann's *Die Sophismatalitteratur des 12.*

und 13. Jahrhunderts, and much work has been done in the last two decades. But there are still a lot of texts to read, edit and analyze.

The bibliography is organized as follows:

- Main texts (in alphabetical order by medieval authors)
- Translations (in alphabetical order by medieval authors)
- Main studies (in alphabetical order by modern authors).

Main texts

Most of the logical and grammatical texts on *sophismata* have been edited by S. Ebbesen and his collaborators in the review *Cahiers de l'Institut du Moyen Age Grec et Latin*, University of Copenhagen. We will here mention only books.

- de Libera, A. *César et le Phénix. Distinctiones et sophismata parisiens du XIIIe siècle.* Centro di cultura medievale, 4; Pisa: Scuola Normale Superiore, 1991.
- De Rijk, L. M. *Some Earlier Parisian Tracts on Distinctiones sophismatum*. Nijmegen: Ingenium Publishers, 1988.
- Scott, T. K. *Johannes Buridanus. 'Sophismata'. Critical Edition with an Introduction.* Grammatica Speculativa, 1; Stuttgart-Bad Cannstatt: Frommann-Holzboog, 1977.
- Pironet, Fabienne. *Iohanni Buridani Summularum Tractatus nonus: De practica sophismatum (Sophismata). Critical Edition and Introduction.* Nijmegen: Ingenium Publishers, forthcoming.
- Kretzmann, N., and Kretzmann, B. E. *The 'Sophismata' of Richard Kilvington.* Oxford: University Press for The British Academy, 1990. (Critical edition.)
- Pinborg, J. *Sigerus de Cortraco, 'Summa modorum significandi sophismata'; New Edition, on the Basis of G. Wallerand's editio prima, with Additions, Critical Notes, an Index of Terms and an Introduction.* Amsterdam: J. Benjamins, 1977.
- Longeway, J. *William Heytesbury: On Maxima and Minima. Chapter 5 of 'Rules for Solving Sophismata', with an Anonymous Fourteenth Century Discussion, a Translation with an Introduction and Study*. Synthese Historical Library, 26; Dordrecht: Reidel, 1984.
- Pironet, Fabienne, *Guillaume Heytesbury, Sophismata asinina. Une introduction aux disputes médiévales. Présentation, édition critique et analyse*. Collection Sic et Non; Paris: Vrin, 1994. (With texts from the *Libelli sophistarum ad usum Oxoniensis.*)

Translations

- Scott, T. K. *Sophisms on Meaning and Truth*. New York: Appleton Century Crofts, 1966. (Translation of John Buridan's *Sophismata*.)
- Biard, J. *Jean Buridan, Sophismes*. Collection Sic et Non; Paris: Vrin, 1993.
- Hughes, G. E. *John Buridan on Self-Reference. Chapter Eight of Buridan's 'Sophismata'. An*

Edition and a Translation with an Introduction and a Philosophical Commentary. Cambridge: Cambridge University Press, 1982. (The paperbound edition omits the Latin text.)

- Kretzmann, N., and Kretzmann, B.E. *The 'Sophismata' of Richard Kilvington.* Cambridge: Cambridge University Press, 1990. (English translation, historical introduction and philosophical commentary.)

Main Studies

Richard Kilvington

Richard Kilvington (ca. 1302-1361), Master of Arts and Doctor of Theology at Oxford, was a member of the household of Richard de Bury, then Archdeacon of London, and finally Dean of Saint Paul's Cathedral in London. Along with Walter Burley and Thomas Bradwardine, he formed the first academic generation of the school known as the ‘Oxford Calculators’. Although he introduced a number of original ideas and methods in logic, natural philosophy, and theology, and influenced his contemporaries and followers, he has been little studied until recently.

Life and Works

Richard Kilvington (we know almost seventy different spellings of his name) was born at the beginning of the fourteenth century in the village of Kilvington in Yorkshire. He was the son of a priest from the diocese of York. He studied at Oxford, where he became Master of Arts (1324/1325) and then Doctor of Theology (ca. 1335). His academic career was followed by a diplomatic and ecclesiastical one. He was in the of service of Edward III and took part in diplomatic missions, culminating in his service as Dean of St. Paul's Cathedral in London. Along with Richard Fitzralph, Kilvington was involved in the battle against mendicant friars. It seems that Kilvington's argument with mendicants continued almost until his death in 1361.

Except for a few sermons, all of Kilvington's known works stem from his lectures at Oxford, and none of these uses the typical late-medieval style in question commentaries, which followed the order of books in the respective works of Aristotle. Rather, in accordance with the fourteenth century Oxford practice, Kilvington reduces the number of topics discussed to some central and probably most important subjects, each of which is constructed as a set of fully developed questions, no more than 10 in each set. This reduction in the range of topics is offset by a lengthier and much more detailed analysis of the particular questions chosen for treatment, some of which print to over 120 pages in modern editions. His

philosophical works, the *Sophismata* and *Quaestiones super De generatione et corruptione,* both composed before 1325, were the result of lectures as a Bachelor of Arts; his *Quaestiones super Physicam* (1325/26) and *Quaestiones super Libros Ethicorum* (1326/1332) come from his period as a Master of Arts; finally, he composed his ten questions on Peter Lombard's *Sentences* in the Faculty of Theology before 1334. (Only the *Sophismata* has been edited and translated, in Kretzmann 1990, 1991; for the titles of other questions and their manuscripts, see Jung-Palczewska 2000b.)

Method in Science

Like a great many Oxford thinkers of the period, Kilvington is convinced that mathematics is useful in any branch of scientific inquiry that deals with measurable subjects. His “measure mania” emerges in his special interest in the problem of change, and in the application of mathematics to determine, that is to “measure”, the phenomenon in question. He makes broad use of the most popular fourteenth-century calculative techniques to solve not only physical but also ethical and theological problems. Four types of calculations can be found in Kilvington's works. The first and most predominant measure, by limits -- i.e., by the first and last instants of the beginning and ending of a continuous process, and by the intrinsic and extrinsic limits of capacities of passive and active potencies -- is not obviously mathematical, but it does raise mathematical considerations insofar as it prescribes a measure for natural processes. The second type of calculation, by latitude of forms, covers processes in which accidental forms or qualities are intensified or diminished, e.g., in the distribution of such natural qualities as heat or whiteness. This is also applied to theology to measure the latitude of moral qualities such as love, grace, sin, will or desire, and to clarify the nature of communication between God and man in general, or between God and the blessed in particular. The third type of calculation is more properly mathematical, and employs a new calculus of compounding ratios in order to measure the speed of local motion. Finally, the fourth type of calculation involves a “rule” that allows one to compare infinities as infinite sets containing infinite subsets, and thereby to determine their relative size. Kilvington finds a way to apply these techniques of measurement in his logical, physical, ethical, and theological writings, and their presence is one of the most distinctive features of his work.

Logic

Kilvington's only logical work is the *Sophismata*. A *sophisma* is neither a standard paradox of disputation nor a sophistical argument but a sentence or proposition whose truth is at issue. The basic structure of the work involves the statement of a *sophisma* sentence, the presentation of a case or hypothesis, arguments for and against the *sophisma* sentence, and finally, the resolution or reply to the *sophisma* sentence and to the arguments on the opposing side.

Kilvington's sophisms are intended to be of logical interest, but they also pose some important physical questions. In constructing his sophisms, Kilvington sometimes appeals to observable physical motion, but just as often makes use of purely imaginary cases having no reference to external reality. Although such cases are physically impossible, they are theoretically possible since they do not involve a formal

contradiction: “and for purpose of the sophisma, that is enough [*unde licet casus idem positus sit impossibilis de facto...tamen per se possibilis est; et hoc sufficit pro sophismate*]” (S 29, p. 69; see also Kretzmann 1990 p. 249).

The first eleven sophisms use the process of whitening to consider the motion of alteration as a successive entity extrinsically limited at its beginning and end. There is no first instant of alteration, claims Kilvington, only a last instant before the alteration begins; likewise, there is no last instant of alteration, only a first instant marking the introduction of the final degree of the quality in question. Thus, motion yields no minimum degree of whiteness or speed, but rather smaller and smaller degrees *ad infinitum* down to zero, since the qualities change continuously. The set of integers is potentially infinite because one can always find a higher integer, but not actually infinite since there is no infinitely great number. Since, in Kilvington's opinion, any continuum of time, space, motion, heat, whiteness, etc., is infinitely divisible, it can be understood quantitatively and measured using infinite sets of integers. Sophisms 29-44 reveal Kilvington's special interest in the causes of local motion, i.e., active and passive potencies, and in effects such as time, distance traversed, and speed. He considers both uniform and difform motion caused by voluntary agents, and calls attention to the dubious measure of instantaneous speed through the comparison of speed in uniform and accelerated motion (see Kretzmann 1982).

The last four sophisms raise issues in epistemology and the logic of knowledge by means of propositions on knowing and doubting involving intentional contexts, e.g., in sophism 45, ‘You know this to be everything that is this’. One of the most interesting historically is sophism 47, ‘You know that the king is seated’, in which Kilvington departs from the usual format to call some of the rules of obligational disputation into question (for discussion, see Kretzmann and Stump 1985; Kretzmann 1990, pp. 330-347).

Natural Philosophy

Although Kilvington does not enjoy the reputation in natural philosophy that he does in logic, recent research has revealed that his questions on Aristotle's *De generatione et corruptione* and *Physics* influenced Thomas Bradwardine's theory of motion and rule concerning velocities in motion (see Jung-Palczewska 2000b). Both works were written before 1328, i.e., before Bradwardine's important treatise, *On the Ratios of Velocities in Motions*.

Like most medieval natural philosophers, Kilvington subscribes to the general Aristotelian principles of motion. He follows Ockham, however, in allowing substance and quality as the only two kinds of really existing thing. The reality of motion is explained in terms of the mobile subject and the places, qualities, and quantities it successively acquires. Consequently, Kilvington is mostly interested in measuring local motion in terms of its actions or causes, the distance traversed and time consumed, rather than the “intensity” of its speed. It is his analysis of local motion that places Kilvington among the 14th-century pioneers who considered the problem of motion with respect to its causes (*tamquam penes causam*), corresponding to modern dynamics, and with respect to its effects (*tamquam penes effectum*), corresponding to modern kinematics.

Unlike many later Oxford Calculators, Kilvington did not advance any clear rules concerning the different kinds of division when examining the dynamical aspect of motion in the problem of setting boundaries to capacities or potencies involved in active/passive processes. But he did articulate most of the issues which were at stake and pose the questions which influenced the solutions of later Calculators (see Wilson 1956, Jung-Palczewska 2000a). Like Heytesbury (for whom, see Longeway 1984) Kilvington pointed to two different considerations which have to be met: one which refers to the everyday use of language, describing real, physical phenomena; and another which refers to a formal, i.e. logico-mathematical, language dealing with the questions in the realm of speculative, i.e., mathematical physics.

Kilvington's belief in the power of mathematics in natural philosophy led him to a new theory of ratios. In order to produce a mathematically coherent theory, he insists (in keeping with Euclid's definition from the fifth book of the *Elements*) that a proper double proportion is the multiplication of a proportion by itself. Moreover, since, in the opinion of Averroes, "the ratio of speeds in motions follows the ratio of the power of the mover to the power of the thing moved", variations in speed must be tied to variations in the proportion of forces and resistances. Consequently, the proper way of measuring the speed of motion is to describe its variations by the double ratio of motive force (F) and resistance (R), as defined by Euclid. The speed of motion thus varies arithmetically, whereas the proportion of force to resistance determining these speeds varies geometrically. Accordingly, when the proportion of force to resistance is squared, the speed will be doubled (for a comprehensive explanation of this new theory see Murdoch and Sylla 1976). Kilvington is aware that a proper understanding of Euclid's definition requires a new interpretation of Aristotle's principles of motion, and concludes that when he is talking about a power moving half of a mobile, Aristotle means precisely the subdouble ratio of F to R, and that when he is talking about power moving a mobile twice as heavy, he means the squaring of the ratio of F to R. Kilvington's function provides values of the ratio of F to R greater than 1:1 for any speed down to zero, since any root of the ratio greater than 1:1 is always a ratio greater than 1:1. Hence, he avoids a serious weakness of Aristotle's theory, which cannot explain the mathematical relationship of F and R in very slow motions.

According to Aristotle, a temporal motion can occur only if there is some resistance playing the role of a *virtus impeditiva*, together with an acting power greater than the resistance of the medium. Since there is no resistance in a vacuum, motion is impossible there. Although he holds that vacua do not exist in nature, he considers the possible temporal motion of both mixed and simple bodies in a vacuum. Kilvington's most interesting and original idea here concerns the possible temporal motion of a simple body. Such a motion could be caused only by internal resistance brought about by the unequal distance traversed by the different parts of a simple body unequally distant from the center of the Earth, relative to which they move. Since the question on motion in a vacuum is posed *secundum imaginationem* and deals with purely imaginable cases, it seems that Kilvington has here combined Aristotelian realism with Ockham's particularist ontology.

Local motion considered in its dynamic aspect, i.e., when speed is proportional to the ratios of Fs to Rs, describes only the value of speed measured at an instant and not successive changes of speed over time. In order to characterize changes of speed in motion, one must study the problem of local motion in its

kinematic aspect. Like all of the later Calculators, Kilvington does not consider speed to be a quality, so there is no real, existential referent for instantaneous speed. Therefore, speed has to be measured by distances, i.e., latitudes of quality (formal distance) or quantity traversed, and such traversals take time unless the speed is infinitely great. In his questions on the *Physics*, Kilvington considers all sorts of motion: uniform, uniformly difform, and difformly difform local motion.

Besides the new function describing the speed of motion, which was eventually adopted and developed by Thomas Bradwardine, one of the most notable achievements of Kilvington's theory of local motion is its awareness of the different levels of abstraction involved in the problem. Although his account frequently proceeds *secundum imaginationem* in the direction of “speculative physics”, it never renounces empirical verification. Kilvington ponders questions which would never arise as a result of direct observation, since the structure of nature can only be uncovered by highly abstract analyses. Such abstractions, however, arise from genuine realities, and cannot contradict them. He saw physics and mathematics as complementary, i.e., as two different ways of describing natural phenomena. Reality provides the starting point for the more complicated mental constructions which in turn make it comprehensible. While mathematics is the proper way to solve these problems, logic remains the most convenient way to pose them. These different methods together guarantee the objective and demonstrative character of the natural sciences. Like other Oxford Calculators, Kilvington refrained from including God in his speculations on natural science, which remained focused on nature as the proper subject of physics. Since the laws of nature are a reflection of God's ordained power, he saw no need to recall this obvious fact while entertaining these laws or considering thought experiments.

On the one hand, Kilvington never abandons the realm of Aristotelian physics or rejects the principles laid down in his natural philosophy. But on the other, his tendency to combine mathematics and physics frequently led him beyond Aristotle's theories to seek solutions to the many paradoxes which resulted from his principles. Kilvington's Aristotelian principles hide essentially Ockhamist views. Despite the fact that he never explicitly mentions the name of Brother William, it is beyond doubt that he not only knew the opinions of the *Venerable Inceptor* but also accepted them as the natural way of understanding the works of the Philosopher.

Impact and Influence

Kilvington's teachings on logic were influential both in England and on the Continent. Richard Billingham, Roger Rosetus, William Heytesbury, Adam Wodeham, and Richard Swineshead were among those English scholars who benefited from Kilvington's *Sophsimata*. His *Quaestiones super De generatione et corruptione* was quoted by Richard FitzRalph, Adam Wodeham, and Blasius of Parma. His *Quaestiones super Physicam* was well known to the next generation of Oxford Calculators: John Dumbleton and Richard Swineshead. It seems that the latter text also influenced Parisian masters such as Nicole Oresme and John Buridan. Thomas Bradwardine, however, was the most famous beneficiary of Kilvington's questions on motion. In his renowned treatise on the velocities of motion, Bradwardine included most of Kilvington's fundamental arguments for a new function describing the relation of motive powers and resistance. Kilvington's other questions on the *Ethics* and the *Sentences* enjoyed a

reputation not only in Oxford but also in Paris, where they were frequently quoted by Adam Junior, John of Mirecourt, Johanes de Burgo, Thomas of Cracow (see Jung-Palczewska 2000b).

Kilvington played an important role in the diffusion of the ideas of early Oxford Calculators, even if Thomas Bradwardine eclipsed him. In his works on the philosophy of nature, he raised many fundamental questions, often solving them in an original and sophisticated manner.

Albert of Saxony

Albert of Saxony (ca. 1316-1390), Master of Arts at Paris, then Rector of the University of Vienna, and finally Bishop of Halberstadt (Germany). As a logician, he was at the forefront of the movement that expanded the analysis of language based on the properties of terms, especially their reference (in Latin: *suppositio*), but also in the exploration of new fields of logic, especially the theory of consequences. As a natural philosopher, he worked in the tradition of John Buridan, and contributed to the spread of Parisian natural philosophy throughout Italy and central Europe.

---

1. Life and Works

Albert of Saxony (*Albertus de Saxonia*), whose family name was Albert of Ricmerstop or Rickmersdorf, is sometimes called *Albertucius* (Little Albert), to distinguish him from the 13th-century theologian Albert the Great. He was born at Helmstedt in present-day Germany around 1316. After initial schooling in the region of Helmstedt, and possibly a sojourn at Erfurt, he made his way to Prague and then on to Paris, where he became a master of arts in 1351. He was Rector of the University of Paris in 1353. He remained in Paris until 1362, during which time he taught arts and studied theology at the Sorbonne, apparently without obtaining any degree in the latter discipline. His logical and philosophical works were composed during this period. After two years of apparently carrying out diplomatic missions between the Pope and the Duke of Austria, he was charged with founding the University of Vienna, of which he became the first Rector in 1365. Appointed canon of Hildesheim in 1366, he was also named Bishop of Halberstadt the same year, fulfilling that office until his death, July 8, 1390.

Not having left any theological writings or commentary on Aristotle's *Metaphysics* (at least none that we

know of), Albert is primarily known for his works on logic and natural philosophy. He also wrote commentaries on Aristotle's *Nicomachean Ethics* and *Economics*, as well as several short mathematical texts (the "Treatise on Proportions" and "Question on the Squaring of the Circle").

Albert's masterwork in logic is a *summa* entitled the *Perutilis logica* (Very Useful Logic). He also composed a voluminous collection of *Sophismata*, in which he examines numerous sentences raising difficulties of interpretation due to the presence of syncategorematic words (i.e., terms such as quantifiers and certain prepositions, which, according to medieval logicians, do not themselves have a proper and determinate signification, but which modify the signification of other terms in a proposition). He also wrote several question commentaries: *Quaestiones* on the *Ars Vetus* or Old Logic (the *Isagoge* of Porphyry and Aristotle's *Categories* and *De interpretatione*), *Quaestiones* and a Commentary on the *Posterior Analytics*, and a series of 25 *Quaestiones logicales* (Logical Questions), addressed to semantic problems and the status of logic. Of dubious authenticity are commentaries on the *Prior Analytics* (both literal and question commentaries), as well as treatises *De consequentiis* (On Consequences) and *De locis dialecticis* (On Dialectical Topics), which have been attributed to him in a Parisian manuscript.

The most renowned philosopher during the era when Albert studied and taught in the Faculty of Arts at Paris was John Buridan. Albert belonged to the first generation of masters who, in one form or another, carried on the tradition of Buridan in logic and natural philosophy. Accordingly, his commentary on the *Posterior Analytics* to a large extent reprises the work of Buridan. At the same time, however, Albert's own work, especially in logic, testifies to the influence of certain ideas and methods developed in England, particularly by William of Ockham, William Heytesbury -- as is apparent in Albert's *Sophismata* -- and Thomas Bradwardine, on the study of movement. Walter Burley was another important influence on Albert. This influence is paradoxical in view of the fact that they had opposing views on the nature of universals, but it is nonetheless in evidence in his commentary on the *Nicomachean Ethics*, and also noticeable in his theory of consequences. Finally, Albert both knew and discussed certain theses of Thomas Maulfelt, who had taught at Paris around 1330. These various influences have sometimes made Albert seem an eclectic compiler -- and not without reason. But, besides making possible several of Albert's own contributions, Albert's eclecticism confers upon him a unique place in the development of logic and philosophy at the University of Paris in the 14th century.

2. Logic

In most respects, the *Perutilis logica* exhibits the influence of Ockham's *Summa logicae*, although it develops in a more autonomous fashion the treatises on obligations, insolubles, and consequences, which had assumed greater importance during this period. As has been known for some time, this work is a remarkable handbook organized into six treatises: the first defines the elements of propositions; the second treats of the properties of terms; the third of the truth conditions of different types of proposition; the fourth of consequences (including syllogisms, and in fact adding to it the theory of topics); the fifth of fallacies; and the sixth of insolubles and obligations.

In the first part of the *Perutilis logica,* which sets out the terminology of the entire text, Albert returns to

the Ockhamist conception of the sign, and so distances himself from the position defended by Buridan. After clearly including the term (an element of the proposition) in the genus of signs -- and thereby providing, in the tradition of Ockham, a semiotic approach to logico-linguistic analysis -- he establishes signification through a referential relation to a singular thing, defining the relation of spoken to conceptual signs as a relation of subordination. He is also Ockhamist in his conception of universals, which he regards as spoken or conceptual signs, and in his theory of supposition, which essentially restates the Ockhamist divisions of supposition. In particular, he preserves the notion of simple supposition -- i.e., the reference of a term to the concept to which it is subordinated, when it signifies an extra-mental thing -- which had been challenged and criticized by Buridan. Finally, Albert is close to the *Venerabilis Inceptor* in his theory of the categories, where, in contrast to Buridan, he refuses to consider quantity as something absolutely real, reducing it instead to a disposition of substance and quality. In doing so, he contributed as much as Ockham to the spread of this model of the relation between substance and quantity in natural philosophy in Paris and Italy.

Albert's treatment of relations is, on the other hand, highly original. Although (like Ockham) he refuses to make relations into things distinct from absolute entities, he clearly ascribes them to an act of the soul by which absolute entities are compared and placed in relation to each other (an act of the referring soul [*actus animae referentis*]). This leads him to reject completely certain propositions Ockham had admitted as reasonable, even if he did not construe them in quite the same way, e.g., ‘Socrates is a relation’. Both Ockham and Buridan had allowed that the term ‘relation’ could refer to the things related (whether connoted or signified) by concrete relative terms (whether collectively or not).

So Albert was not content with merely repeating Ockhamist arguments. More often than not, he developed and deepened them, e.g., in connection with the notion of the appellation of form. This property of predicates, which had previously been used by the *Venerabilis Inceptor*, was employed by Albert in an original manner when he turned to it, in place of Buridan's appellation of reason (*appellatio rationis*), to analyze verbs expressing propositional attitudes. Every proposition following a verb such as ‘believe’ or ‘know’ appellates its form. In other words, it must be possible to designate the object of the belief via the expression understood as identical to itself in its material signification, and without reformulation. Another area in which Albert deviates from Ockham is in his rejection of the idea that any distinction with multiple senses must have an equivocal proposition as its object. According to Albert, equivocal propositions can only be conceded, rejected, or left in doubt.

Albert's semantics becomes innovative when he admits that propositions have their own proper significate, which is not identical to that of their terms (see especially his *Questions on the Posterior Analytics* I, qq. 2, 7, 33). Like syncategorematic terms (see his *Questions on the Categories*, qu. 1 ‘On Names’), propositions signify the “mode of a thing [*modus rei*]”. Nevertheless, Albert avoids hypostatizing these modes, in the final analysis explaining them as relations between the things to which the terms refer. It cannot be said here that Albert is moving towards the “complexly signifiable [*complexe significabile*]” of Gregory of Rimini, although his remarks are reminiscent of the latter theory. Still, he uses the idea of the signification of a proposition to define truth and to explain ‘insolubles’, i.e., propositions expressing paradoxes of self-reference. On Albert's view, every proposition signifies that it is true by virtue of its form. Thus, an insoluble proposition will be false because it signifies at the same

time that it is true and that it is false.

In his *Sophismata*, Albert usually follows Heytesbury. The distinction between compounded and divided senses, which is presented in a highly systematic way in Heytesbury's *Tractatus de sensu composito et diviso*, is the primary instrument (besides the appellation of form) used to resolve difficulties connected with epistemic verbs, and with propositional attitudes more generally. This is abundantly clear in his discussion of infinity. Rather than appealing to the increasingly common distinction between the categorematic and syncategorematic uses of the term ‘infinite’, and then indicating the different senses it can have depending upon where it occurs in a proposition, he treats the infinite itself as a term. Albert's approach involves giving the analysis of the logical and linguistic conditions of every proposition involving the term ‘infinite’ that is significant and capable of being true. This leads him to sketch a certain number of possible definitions (where he appears to take into account the definitions of Gregory of Rimini), but also to raise other questions, e.g., on the relation between finite and infinite beings (in propositions such as ‘infinite things are finite [*infinita sunt finita*]’), on the divisibility of the continuum, and on qualitative infinity. There are echoes in Albert not only of the approach Buridan had, for his part, systematically implemented in his *Physics*, but also of the analyses of English authors -- again, especially Heytesbury. As is often the case, the treatment proposed by Albert in the *Sophismata* is quick and a little eclectic, but it provides good evidence of the extent to which questions about the infinite were discussed at the time.

Finally, one of the fields in which Albert is considered a major contributor is the theory of consequences. In the treatise of the *Perutilis Logica* devoted to consequences, Albert often seems to follow Buridan. But whereas Buridan maintained the central role of Aristotelian syllogistic, Albert, like Burley, integrated syllogistic and the study of conversions into the theory of consequences. Consequence is defined as the impossibility of the antecedent's being true without the consequent's also being true -- truth itself being such that howsoever the proposition signifies things to be, so they are. The primary division is between formal and material consequences, the latter being subdivided into consequences *simpliciter* and *ut nunc*. A syllogistic consequence is a formal consequence whose antecedent is a conjunction of two quantified propositions and whose consequent is a third quantified proposition. Albert is thus led to present a highly systematized theory of the forms of inference, which represents a major step forward in the medieval theory of logical deduction.

3. Natural Philosophy

It is this analysis of language together with a particularist ontology that places Albert in the tradition of nominalism. This is combined with an epistemological realism that emerges, e.g., in his analysis of the vacuum. In certain respects, Albert's work is a proper extension of physical analysis to imaginary cases. Distinguishing, as Buridan did, between what is absolutely impossible (i.e., the contradictory) and what is impossible “in the common course of nature” (*Questions on De Caelo* I, qu. 15), he considers hypotheses under circumstances which are not naturally possible but imaginable given God's absolute power (e.g., the existence of a vacuum and the plurality of worlds). However, even if we can imagine a vacuum existing by divine omnipotence, no vacuum can occur naturally (*Questions on the Physics* IV,

qu. 8). Albert refuses to extend the reference of physical terms to supernatural, purely imaginary possibilities. In the same way, one can certainly use the concept of a point, although this would only be an abbreviation of a connotative and negative expression. There is no simple concept of a point, a vacuum, or the infinite, and although imaginary hypotheses provide an interesting detour, physics must in the end provide an account of the natural order of things.

Historically, Albert does not enjoy the reputation in natural philosophy that he does in logic. His commentaries on the *Physics* and on the treatise *De caelo* are close to Buridan's, and Albert appeals to the authority of his “revered masters from the Faculty of Arts at Paris” at the beginning of his questions on *De caelo*. Even so, it should be noted that his *Physics* was written before the final version of Buridan's *Questions on the Physics* (between 1355 and 1358), which means that he could not have benefited from the final version of Buridan's lectures.

We have already seen that on the question of the status of the category of quantity, then at the forefront of logic and physics, Albert followed Ockham and distanced himself from Buridan by reducing quantity to a disposition of substance or quality. This move becomes evident in certain physical questions, e.g., in the study of condensation and rarefaction, where Albert openly disagrees with his Parisian master by arguing that condensation and rarefaction are possible only through the local motion of the parts of a body, and without needing to assume some quantity that would have a distinct reality on its own. Nevertheless, he defines the concept of a “lump of matter [*materie massa*]” without giving it any autonomous reality, although it does help fill in the idea of a ‘quantity of matter’, which Giles of Rome had already distinguished from simple extension.

Similarly, Albert is sometimes seen as standing alongside Ockham on the nature of motion, rejecting the idea of motion as a flux (*fluxus*), which is the position Buridan had adopted. In contrast to his master, Albert treats locomotion in the same way as alteration (movement according to quality): in neither case is it necessary to imagine local motion as a *res successiva* distinct from permanent things, at least if the common course of nature holds and one does not take into account the possibility of divine intervention.

As far as the general principles of motion are concerned, Albert, like Nicole Oresme, follows Thomas Bradwardine on the relation of motive force and resistance. On the other hand, when he considers the movement of projectiles, gravitational acceleration, and the movement of celestial bodies, Albert adopts Buridan's major innovation, i.e., the theory of *impetus*, a quality acquired by a moving body (see Buridan's *Questions on the Physics* VIII, qu. 13, on projectile motion). Like Buridan, he extends this approach to celestial bodies in his commentary on *De caelo*, clearly following its consequences in rejecting intelligences as agents of motion and in treating celestial and terrestrial bodies using the same principles. Nevertheless, he formulates the idea of *impetus* in more classical terms as a *virtus impressa* (impressed force) and *virtus motiva* (motive force). Albert makes no pronouncements about the nature of this force. This is a question for the metaphysician. His work also mentions the mean speed theorem, a method of finding the total velocity of a uniformly accelerated (or decelerated) body, which had been stated (without being demonstrated) in Heytesbury's *Tractatus de motu*, and also adopted by Nicole Oresme. Albert was part of the general scientific trend which sought the first formulations of the principles of dynamics.

As for his commentaries on Aristotle's works of natural philosophy, Albert wrote a *Treatise on Proportions* that was devoted to the analysis of movement. This was very much inspired by Bradwardine's treatise *De proportionibus velocitatum in motibus*, and extended the work he and others had begun at Oxford. Albert's texts on the kinematic measure of both rectilinear and circular motion enjoyed a broad popularity. Finally, he explained a number of curious natural phenomena, taking particular interest in earthquakes, tidal phenomena, and geology.

Like his master Buridan, Albert was interested in certain mathematical problems. To this end, he wrote a question on the squaring of the circle as well as questions on John of Sacrobosco's *Treatise on the Sphere*. In addition to authoritative arguments and purely empirical justifications, his question on the squaring of the circle uses properly mathematical arguments that appeal to both Euclid (in the version of Campanus of Novarra) and Archimedes (translated by Gerard of Cremona). His most original contribution consists in a proposal to dispense with Euclid's proposition X.1, replacing it with a postulate stating that if A is less than B, then there exists a quantity C such that $A<B<C$.

4. Impact and Influence

Albert of Saxony's teachings on logic and metaphysics were extremely influential. Although Buridan remained the predominant figure in logic, Albert's *Perutilis logica* was destined to serve as a popular text because of its systematic form and also because of the fact that it takes up and develops essential aspects of the Ockhamist position. But it was his commentary on Aristotle's *Physics* that was especially widely read. Many manuscripts of it can be found in France and Italy, in Erfurt and Prague. Albert's *Physics*, more than Oresme's and even Buridan's, basically guaranteed the transmission of the Parisian tradition in Italy, where it was used alongside the works of Heytesbury and John Dumbleton. His commentary on Aristotle's *De caelo* was also influential, eventually eclipsing Buridan's commentary on this text. Blasius of Parma read it in Bologna between 1379 and 1382. A little later, it enjoyed a wide audience at Vienna.

Albert played an essential role in the diffusion throughout Italy and central Europe of Parisian ideas which bore the mark of Buridan's teachings, but which were also clearly shaped by Albert's comprehensive grasp of English innovations. At the same time, Albert was not merely a compiler of the work of others. He knew how to construct proofs of undeniable originality on many topics in both logic and physics.

Richard the Sophister

Richard the Sophister (Richardus Sophista) was an English philosopher/logician who studied at Oxford most likely sometime during the second quarter of the thirteenth century. Richard's identity is uncertain, but he is known to be the author of a collection of logically puzzling sentences, sometimes called "sophisms", entitled *Abstractiones*. The puzzling aspect of these sophisms is variously caused by semantic or syntactic ambiguities involved in certain logical or "syncategorematic" words such as "all", "every", "or", "if...then", "and", "not", "begins", "ceases", "except", "necessary", "possible" etc.

Abstractiones

The title "*Abstractiones*" was apparently meant to capture the "excerpted" nature of this collection of sophisms that are presented in a somewhat summary fashion.[1] This collection of sophisms became a kind of logical textbook used to teach students to identify sophistical fallacies. This book was probably used in several medieval universities for several decades, from the late thirteenth well into the fourteenth centuries. Richard is often referred to as "Magister Abstractionum" or "Magister Richardus Sophista" to give emphasis to the masterful, albeit summary, treatment of a very large collection of over three hundred such sophism sentences.[2] The title "*sophista*" simply meant "logician".

The seven known manuscripts of the *Abstractiones* date from the late thirteenth to the early fourteenth centuries:[3]

Ms B = Brugge, Stedelike Bibliotheek, 497
Ms C = Oxford, Corpus Christi College, E 293B
Ms D = Oxford, Bodleian Library, Digby 24

Ms K = København, Det Kongelige Bibliotek, Fragm.1075
Ms O = Oxford, Bodleian Library, Digby 2
Ms P = Paris, Bibliothèque Nationale lat. 14069
Ms R = London, British Library, Royal 12.F.xix

Only two of these manuscripts (B, D) are complete; the remaining five are in varying degrees of fragmentation. Two manuscripts (O, R) appear to be derivative texts, or redactions, of the *Abstractiones*.

The dating of the composition of the *Abstractiones* appears to have been around the 1230's or 40's. Earliest references to the *Abstractiones* appear from the late thirteenth century in a manuscript at Worcester Cathedral Library, Q. 13, which is confidently dated no later than 1295, and probably as early as 1270.[4] Worcester Q. 13 contains four references to the "Magister Abstractionum". Another reference to the *Abstractiones* can be found in a Quodlibetal Question of William of Alnwick, "Does God know infinitely many things (*Utrum Deus cognoscat infinita)*?", q. 9 probably dating from around 1320. Walter Burley's tract, *De Exceptivis*, edited by L. M. de Rijk, contains a reference to the Magister Abstractionum.[5] An interesting reference can also be found in William of Ockham's *Summa Logicae* and additional references can be found in Ps. Richard of Campsall, John of Reading and Adam Wodeham.[6]

The fact of the existence of two derivative texts of the *Abstractiones* as well as the numerous known references by accomplished logicians some seventy years after its composition indicate that the *Abstractiones* was a quite popular book that survived the test of time. Although as compared to sophism literature of the fourteenth century Richard's analysis of sophisms appears somewhat unsophisticated, as compared to treatments of sophisms of his contemporaries Richard's analyses are qualitatively similar. Richard's greatest accomplishment lay, perhaps, in his ability to encapsulate and summarize a huge number of such logical puzzles, presenting for the student a handy reference book filled with examples of a host of logical fallacies.

Examples of Sophisms

In order to give the reader a better understanding of the content of this book of *Abstractiones*, it might be helpful to list a few examples of the sophism sentences discussed in it and to illustrate Richard's treatment of just one of these. As noted above, our book contains over three hundred sophism sentences. A random sampling includes these examples:

(1) Every man is every man (*Omnis homo est omnis homo*)

(16) Whatever exists or does not exist exists (*Quicquid est vel non est est*)

(39) Everything other than an animal which plus Socrates are two differs from Socrates (*Omne aliud quam animal quod et Sortes sunt duo differt a Sorte*)

> (79) The whole Socrates is less than Socrates (*Totus Sortes est minor Sorte*)
>
> (96) If you know that you are a stone you do not know that you are a stone (*Si tu scis te esse lapidem tu non scis te esse lapidem*)
>
> (157) Nothing is true about nothing (*De nihilo nihil est verum*)
>
> (187) You have not ceased to eat iron (*Tu non cessas comedere ferrum*)
>
> (215) All ten except one are nine (*Omnia X praeter unum sunt IX*)
>
> (278) It is impossible that you know more than you know (*Impossibile est te scire plura quam scis*)

From the above rather small list of sophisms, it can already be noticed that some sentences are more complex, and thus more logically puzzling, than others. Some sentences do not seem puzzling in themselves at all, but become puzzling only within a certain "context" that is set up within which arguments proving and disproving the sophism must be developed. Such a context was called a "*casus*".[7] It seems likely that the proving and disproving of the sophism sentence was done along the lines of a medieval oral "*disputatio*" within the classroom setting. This is the way Richard writes up his summaries: Proposal of the sophism, sometimes within a *casus*; arguments establishing the truth of the sentence; arguments establishing the falsity of the sentence; resolution of the sophism along with identification of the sophistical fallacy involved.

The very first sophism sentence treated is one of the least complicated (this sophism involves no *casus*):

> Every man is every man
>
> Proof: This man is this man, that man is that man and so forth for each individual man, therefore every man is every man.
>
> Another proof: No proposition is more true than one in which the same thing is predicated of the same thing....
>
> Disproof: This proposition is true, "some man is not every man" and, similarly, "no man is every man"; therefore it is false that every man is every man.
>
> Solution: The solution to the sophism is to note that "every man" is equivocal as to reference to every man taken singularly (as in "any man") and as to every man taken as a whole (as in "all men"). Mixing the two senses of "every" from subject to predicate causes the logical puzzle.

As noted, this sophism sentence is relatively uncomplicated and it is easy to spot the obvious fallacy involved, but Richard's text proceeds with increasingly more difficult and intricate sophism sentences, many of which engage the mind in complex mental acrobatics. The fallacies noted throughout are the standard ones discussed in Aristotle's *De Sophisticis Elenchis*: the fallacy of equivocation; the fallacy of accident; the fallacy of the composite and divided senses; the fallacy of the consequent; the fallacy of absolute and qualified senses; the fallacy of many causes of truth; amphiboly; improper supposition.

Richard's Identity

There is still no certainty as to the identity of the Magister Abstractionum. Because of the colophon appended to the two complete manuscripts of the *Abstractiones*, we know, of course, that his name was "Richard":

> *Expliciunt ista, quae tu, Ricarde Sophista,*
> *fecesti, morum flos et doctor logicorum.*
> *Dirige scribentis, Spiritus alme, manum.*
> *Expliciunt Abstractiones*.
> (Digby 24, f.90rb)
>
> (These [sophisms] are complete, which you, Richard the Sophister,
> Flower of virtue and teacher of logic, have produced.
> Turn the scribe's hand [from its task], nurturing Spirit.
> The *Abstractiones* are complete.)

De Rijk suggested the name Richard Fishacre, disagreeing with the suggestion of Richard Fitz-Ralph offered by Macray on the basis that the dating of the text within the second quarter of the thirteenth century is more consistent with Fishacre's chronology.[8] Jan Pinborg suggested the name Richard Rufus also on grounds that the dating of the *Abstractiones* is consistent with Rufus' being at Oxford.[9] It is generally assumed that the author is English. Pinborg offered one further bit of evidence for the name Richard Rufus in that there is some reason to think that certain doctrines of Richard Rufus, as criticised by Roger Bacon, are in the *Abstractiones*. The primary doctrine in question attributed to Richard Rufus and criticised by Roger Bacon is, in general terms, that the signification of a name can remain in the absence of any actual thing signified by that name, although, as Bacon suggests, the proponents of this view must supply some kind of "habitual being" for the lost actual significate of such names. It is this doctrine of the "*esse habituale*" that Bacon finds objectionable. That Richard Rufus does seem to have such a doctrine appears clear in his discussion of the question "Whether Christ while three days in the tomb was a man" ("*Utrum Christus in triduo mortis fuerit homo*") in distinction 22, book III of his *Sentences Commentary*.[10]

It would be beyond the scope of this essay to deal with the complexities of both Richard Rufus' treatment

of this question as well as Roger Bacon's voiceful criticisms of the notion of the "*esse habituale*". The important question here is whether the doctrine espoused by Richard Rufus exactly parallels anything that can be found in the *Abstractiones* of Richard the Sophister. It is important to find not only terminological similarities but also doctrinal similarities. The terminology within which Richard Rufus makes the above noted distinction is "*esse in habitu*" versus "*esse in actu*", the former he also labels "*esse simpliciter*", the latter "*esse ut nunc*".[11] Bacon seems to substitute the expression "*esse habituale*" for the expression "*esse in habitu*". Rufus does not use the expression "*esse habituale*". As referenced above, Pinborg noticed the expressions ",i>esse consequentiae sive habitudinis" and "*esse quod est operatio entis*" in the Abstractiones. Bacon also uses the expression "*esse habitudinis*", but he seems to recognize a distinction between "*esse habituale*" and "*esse habitudinis*"; the latter, he says, "is used about propositions and will be destroyed later when there is talk about propositions".[12] This remark might indicate that Bacon finds the same doctrinal problem with the "*esse habitudinis*" that he finds with the "*esse habituale*" (i.e., it introduces a foil for some kind of fictive being), but we cannot be certain of this, since he never returned to this topic in the Compendium. Richardus Sophista does not use the terminology of "*esse habituale*/*esse actuale*", "*esse in habitu/esse in actu*" that we find in Bacon and Rufus respectively.[13] Pinborg also noted that William of Ockham criticizes those who make the distinction between "*esse consequentiae sive habitudinis*" and "*esse quod est operatio entis*" as ignorant of the simple distinction between hypothetical and categorical propositions, which according to Ockham is all that the distincition amounts to.[14] Pinborg sees Ockham's criticism as possibly making the same point as Bacon, i.e., the terminolgy invites some kind of talk of fictive being. Although Ockham is probably right to want to eliminate the old terminology in favor of less problematic language, the important questions are whether Richard the Sophister's use of the distinction "*esse habitudinis*/*esse quod est operatio entis*" entails anything other than a distinction between types of propositions and whether his use of the distinction comes under the attacks of Roger Bacon on the same way in which these attacks seem relevant to a terminologically similar distinction in Richard Rufus.

A complete answer to these questions would require not only a detailed examination of the use of this distinction in the resolution of sophisms in the *Abstractiones*, but also an examination of Richard's position regarding terms that "assert non-being" and his account of negation and negatives generally.[15] These tasks are clearly beyond the scope of this essay. With respect to the first question, it will have to suffice to record here that there are only three places in the *Abstractiones* where Richard employs the distinction in the resolution of sophisms and in none of these is it clear that this is his favored solution.[16] More importantly, Richard's use of the distinction in the resolution of sophisms seems to match the use made of the same distinction (under the terminology "*esse habituale*/*esse actuale*") by William of Sherwood, that is, as essentially a way of marking a distinction between hypothetical and categorical propositions.[17] It has been successfully argued by Braakhuis that the attacks of Roger Bacon do not apply to William's use of the distinction, even though, of all the authors noted so far, only William's terminology is exactly the same terminology used by Bacon.[18] Thus, if the doctrine under attack by Bacon cannot be attributed to William, neither can it be attributed to Richard the Sophister. It appears, then, that Richard Rufus and Richard the Sophister cannot be identified, at least on the basis of these alleged doctrinal and terminological similarities.

Stanford Encyclopedia of Philosophy
Notes to Richard the Sophister

Notes

[1.] In Albert of Saxony's introductory remarks regarding the exceptive term "*tantum*" in his *Perutilis Logica* we read this definition of the term "*abstractio*": "*Abstractio est dubitabilium propositionum collectio* (An abstraction is a collection of puzzling propositions)" (Erfurt ms., Amploniana, Cod. Q 242, f. 33v). This section of Albert's treatise is not edited in the 1518 Venice edition. The only other known treatise from the Middle Ages with the title "*Abstractiones*" is that of a certain Hervaeus Sophista, edited in de Libera 1986. The term "*abstractio*", then, seems to refer to a "collection" of sophisms, perhaps with some emphasis upon the "excerpted" nature of such a collection. Indeed, the collection of Hervaeus consists of some 298 sophisms within a space of a mere five folios. Richard considers some 305 sophisms within a space of almost thirty folios in the Digby 24 manuscript.

[2.] De Rijk 1962-67, Vol. II, pt 1., 62-85 and 444-447.

[3.] For a description of manuscripts B, D, O, P and R see de Rijk 1962-67. De Rijk was unaware of manuscripts C and K. For a brief description of the C manuscript, see P.O. Lewry, "Oxford Logic 1250-1275: Nicholas and Peter of Cornwall," in Lewry 1985, 22. For additional descriptions of these manuscripts, see Raedts 1987, 107-111.

[4.] Ebbesen 1987, 136 and Lewry 1985. The manuscript is dated 1295, but Lewry remarks that the author uses the example "*Henricus est rex Angliae*", and Henry died in 1272. Thus the reference to the Magister Abstractionum could be as early as the 1270's.

[5.] De Rijk 1986: 27.

[6.] William of Ockham, *Summa Logicae*, ed. Philotheus Boehner, Gideon Gál, and Stephen Brown (St. Bonaventure, N.Y. 1974), 367. Although this appears to be the only place where Ockham refers explicitly to the Magister Abstractionum, the editors point to other places where they believe he clearly has the Magister in mind (e.g., *Summa Logicae* III-1, c.16, 405; II, c. 4, 262). For references in Campsall, John of Reading and Adam Wodeham, see the Introduction to the *Summa Logicae*, 51*, n. 17.

[7.] The setting up of "contexts (*casus*)" within which proponents and opponents were obliged to develop their respective arguments gave rise to a special genre of sophism literature called "*obligationes*". We note the techniques of "*obligatio*" especially in the development of sophisms towards the end of the *Abstractiones*. For a discussion of the historical development of obligations, see Stump 1982 and Spade

1982.

[8.] De Rijk 1962-67, Vol. II, 71.

[9.] Pinborg 1976, 1-4.

[10.] The text of this question can be found in Franz Pelster, "Der Oxforder Theologie Richardus Rufus O.F.M. über die Frage, '*Utrum Christus in triduo mortis fuerit homo*'", *Recherches de Théologie Ancienne et Médiévale*, 16 (1949), 259-280. For Bacon's discussion, see Thomas S. Maloney (ed. & tr.), *Roger Bacon, Compendium of the Study of Theology*, Studien und Texte zur Geistesgeschichte des Mittelalters 20, (Leiden: E. J. Brill, 1988), par. 86-101.

[11.] Pelster 1949: p. 279, ll. 136-144.

[12.] Bacon, *Compendium*, trans. Maloney 1988: par. 103: "*Sed adhuc cavillant de esse habitudinis, sed hoc in propositione habet locum, et ideo destruetur postea, cum de propositionibus fiet sermo*". It is worth noting here that Maloney translates "*esse habituale*" and "*esse habitudinis*" identically as "habitual being", but there is warrant from Bacon himself that these are different notions and, perhaps, therefore, should be translated differently.

[13.] In connection with this terminology, Lewry (1985, p. 22) incorrectly transcribes C 283B at folio 207va as "*esse habituale sive commune*", (thus perhaps seeing the terminology found in Bacon's criticism of Rufus) whereas the scribe of the *Abstractiones* clearly writes "*esse habitudinis sive consequentiae*".

[14.] Ockham, (ed. Boehner et al.,) p. 263.

[15.] Especially relevant here would be a study of the sophism OMNIS PHOENIX EST, where Lewry (1985) p. 22, sees possible evidence of the Magister adopting notions criticized by Bacon.

[16.] These are in connection with the following sophisms: (1) OMNE COLORATUM EST: The distinction is introduced as a way of explaining a perceived mistake in one of the arguments in the disproof of the sophism, i.e., "*Omne coloratum est. Omne album est coloratum. Ergo omne album est*". It is said that this argument equivocates upon "*esse*", for in the first premiss it is "*esse operatio entis*", whereas in the second it is "*esse habitudinis sive consequentiae*". Richard goes on to interpret the former categorically, the latter hypothetically. Ockham's criticisms (noted above) seem relevant here in that equivocation is a semantic fallacy, whereas the propositional distinction is essentially syntactic. As Ockham notes, any proposition can be turned into one or the other. The important observation, however, is that Richard is not adopting the distinction as a favored solution to the sophism itself, but only as what some people say about a mistake in the disproof of an argument. (2) OMNIS HOMO DE NECESSITATE EST ANIMAL: Here too he offers multiple solutions to the sophism, the second of which is again to note the fallacy of equivocation in connection with "*esse*", as above. Here, however, it

seems clear that this is not his favored solution to the sophism. Rather he argues the sophism is best solved through application of the composite and divided senses of "*necessitas*". (3) OMNIS ASINUS EST HOMO: Here the distinction is offered again as an explanation of a kind of equivocation between two premises of the argument, as in: "*Omne animal est homo. Omnis asinus est animal*. *Ergo omnis asinus est homo*".

[17.] The distinction can be found in Norman Kretzmann (tr.), *William of Sherwood's Introduction to Logic*, (Minneapolis: University of Minnesota Press, 1966), 125-126, and Kretzmann (tr.), *William of Sherwood's Treatise on Syncategorematic Words*, (Minneapolis: University of Minnesota Press, 1968), 92-93.

Medieval Theories of Properties of Terms

The theory of properties of terms (*proprietates terminorum*) was the basis of the medievals' semantic theory. It embraced those properties of linguistic expressions necessary to explain truth, fallacy and inference, the three central concepts of logical analysis. The theory evolved out of the work of Anselm and Abelard at the turn of the twelfth century, developed steadily through the thirteenth and fourteenth centuries and was still undergoing changes in the fifteenth and sixteenth centuries. It is generally agreed that its early stages were closely bound up with the theory of fallacies, but as a general semantic theory, it developed in response to a variety of needs, and one mistake of modern attempts at interpretation is to seek a unique rationale of one notion or another. Each notion evolved continually, satisfying one need at one time and another at a later date, and often several conflicting needs at the same time. Another mistake is to try to map each notion *seriatim* onto corresponding notions in contemporary semantic theory, but although one can see analogies and similarities, none of the medieval "properties" matches exactly any modern notion.

---

1. Historical Survey

William of Sherwood, writing from an Oxford perspective in the 1240s, identified four properties of terms: signification, supposition, copulation and appellation: "There are four properties of terms that we intend to distinguish now ... These properties are signification, supposition, copulation, and appellation" (tr. Kretzmann, p. 105).[1] A different tradition is represented by Peter of Spain and Lambert of Auxerre,

namely, that of Paris. Lambert identifies five properties of terms: supposition, appellation, restriction, distribution and relation: "Now, there are many properties of terms: supposition, appellation, restriction, distribution [distinction], and relation ... But because signification is, as it were, the fulfillment of a term, and the properties of terms are founded on signification, for the sake of clarity in what follows we must at the outset consider what the signification of a term is, and how it differs from supposition", tr. Kretzmann and Stump, p. 104.[2] In his treatment he includes ampliation (a correlative to restriction) and thereby matches the sections in Peter of Spain's *Tractatus*: *De suppositionibus* (On Suppositions), *De relativis* (On Anaphora), *De ampliationibus* (On Ampliations), De appellationibus (On Appellations), *De restrictionibus* (On Restrictions), *De distributionibus* (On Distribution).

To these must be added further properties of terms which were important in the theory's gestation in the twelfth century but were later no longer included as distinct properties: univocation, equivocation, adjectivation, substantivation and so on. From the fourteenth century onwards, other properties were also abandoned, so that finally the important lasting properties were signification, supposition, ampliation and restriction, and the supposition of relatives.

Given the central importance which it later attained, it is surprising how late supposition was in being identified as one of the properties of terms. In the twelfth century, the primary distinction was that between signification, or univocation, and appellation. As early as Anselm's *De Grammatico* we find a distinction between *significare per se* (signify as such) and *significare per aliud* (signify relatively). The latter was also known as *appellare* (to name or appellate). Whereas in the former (*per se*) what was signified was a form, in the latter what was signified, or appellated, was a thing. A single form is common to a number of things we call by the same name, so one crucial problem in the philosophy of language is to understand how the different uses of a name are unified in the face of the distinctness of the many individuals talked about. In this way, we can understand the importance played in the twelfth century of univocation in contrast with appellation. Proper names, naming single items, are contrasted with appellative names, naming many. Univocation is the signification of a univocal word, described in the *Fallacie Parvipontane* as "a variation in the supposition/appellation of a name while keeping the signification the same" (my translation).[3]

Throughout much of the twelfth century, 'supposition' retained the linguistic sense it had had since at least the time of Priscian (4th century CE), namely, the placing of a name as subject. The relation of that name as subject to the thing named was called its appellation. This was the ability of a univocal appellative noun to name different things. The appellation of a name was not fixed, however. It could be ampliated or restricted by the predicate. So, for example, the predicate '*opinabilis*' (credible) ampliates or extends the appellation of a name such as 'man' to cover a wider range, perhaps of no longer existing men, or of men who might have existed, or who might exist in the future. Thus, appellation came to mean the present correct application of a term (William of Sherwood, p. 74), which could be ampliated, or even restricted by, say, the apposition of an adjective: 'white man' appellates only white men, not all even presently existing men.

Later, however, 'supposition' came to replace 'appellation', and the latter term underwent its own

transformation. Supposition became the major property of an occurrence of a term in a proposition (including now predicates, and even parts of predicates), distinguishing what in particular was being spoken of on some occasion of utterance by some particular use of a word, from that word's general property (signification) of meaning. The term 'man' signifies the form of man wherever the term occurs, but each occurrence of the term 'man' supposits for (the individuals in) possibly distinct classes or groups of men (but note that it supposits for the men, not the classes).

Given the literal meaning of '*supponere*' as "acting as subject", it is unsurprising that several authors, even as late as Vincent Ferrer in the 1370s, restricted supposition to subject terms, preferring to speak instead of copulation as the corresponding property of the predicate. Those reservations aside, however, the natural similarity in function of subject and predicate in picking out varying classes of things while remaining a univocal term, led most authors to extend the notion of supposition to all terms. At the same time, talk of univocation was superseded by signification, by implication univocal signification unless equivocation was identified.

A major shift in focus occurred in the early fourteenth century, probably occasioned by William of Ockham -- certainly, he was the leading figure. On the one hand, signification came to be understood entirely extensionally, given Ockham's antipathy towards real universals. Accordingly, what was taken to be signified by a term were the things of which it can be truly predicated instead of a form or property which they share. For example, where before the term 'man' was taken to signify humanity, and 'white' whiteness, for Ockham the former signifies (all) men and the latter all white things. From this perspective, the contrast found in thirteenth century authors between (as Peter of Spain called it) natural supposition versus accidental supposition, becomes redundant. Natural supposition was the term's extension, accidental supposition that range of things it supposited for in a particular proposition. For Peter, the term signifies a form, and supposits naturally for a class of objects, whereas an occurrence of the term supposits accidentally on an occasion of use for a group of those objects. For Ockham, the term signifies that class, the form being no more than a *fictum* (a figment of the mind) or (in his later works) the mental act (of conceiving of those things) itself. Thus natural supposition (William of Sherwood calls it habitual supposition, the *Tractatus de proprietatibus sermonum*, absolute supposition) drops out as unnecessary.

From the early fourteenth century, supposition came to dominate among the properties. Ampliation and restriction were already functions of supposition (or appellation as it had been), copulation as the naming function of predication is subsumed under supposition, and *relatio*, the connection of anaphoric terms to their antecedents, becomes a discussion of the supposition of those terms. Finally, distribution is treated as a particular mode or type of supposition, confused and distributive supposition. Indeed, in the final phase, it could seriously be asked if supposition was indeed a property of terms, as does Albert of Saxony. For like others, he defines supposition as '*acceptio termini*' (the act of acceptance of a term) of various kinds, and so is as much a property of the speaker as of a term.

2. Signification

Signification contrasts with the other properties of terms in one major respect, for the other properties (perhaps with the exception of appellation in some authors, and natural supposition) are all properties of terms relative to their occurrence in particular propositions -- indeed, they are properties of occurrences of terms. Signification, however, is had by a term prior to its particular uses or occurrences: "Now signification differs from supposition in that signification is prior to supposition", tr. Kretzmann and Stump, p. 105.[4] Indeed, the other properties are dependent on the signification of the term. For example, an occurrence of a term can only supposit for certain objects in virtue of its signifying them, among others, or signifying some property they share.

A twelfth century commentary on the *Perihermeneias* says that at the time of Aristotle, there was a great debate over the principal signification of utterances: was it '*res*' (things) or incorporeal natures (Plato) or *sensus* (sensations) or *imaginationes* (representations) or *intellectus* (concepts)? In fact, medieval philosophers of language were heir to two conflicting semantic theories. According to Aristotle, the greatest authority from the ancient world, words name things by signifying concepts in the mind (Boethius translated his term as *passiones animae* -- affections of the soul) which are likenesses abstracted from them. But Augustine, the greatest of the Church fathers, had held that words signify things by means of those concepts. This led the medievals to the question: do words signify concepts or things? The question had already been asked by Alexander of Aphrodisias and his answer was transmitted to the medievals in Boethius' second commentary on Aristotle's *Perihermeneias* (*De Interpretatione*): "Alexander asked, if they are names of things, why does Aristotle say that they are primarily signs of concepts ... He says that although spoken words are names of things, we do not use them to signify things, but [to signify] those affections of the soul which are produced in us by them", my translation. [5] So words primarily signify concepts.

But the matter was not settled, other than that whatever view a medieval philosopher took, it had to be made to accord with the authority of Aristotle, perhaps *in extremis* by reinterpreting Aristotle's words. Abelard refers to a distinction between *significatio intellectuum* (signification of concepts) and *significatio rei* (signification of the thing), more properly called nomination or appellation (see De Rijk, *Logica Modernorum*, vol. II(1), pp. 190-9). Similarly, the *Tractatus de proprietatibus sermonum* asks whether words signify concepts (*intellectuum*) or things, and responds: both, but primarily a thing via a concept as medium (op.cit. II (2), p. 703).

A particular novelty of the thirteenth century, however, was to conceive of the concept itself as a sign. We find this in Lambert of Auxerre: "The signification of a term is the concept of a thing, a concept on which an utterance is imposed by the will of the person instituting that term. For, as Aristotle maintains in the first book of *De Interpretatione* (16a3-5), utterances are signs of states in the soul -- i.e., in the understanding -- but concepts are the signs of things", tr. Kretzmann and Stump, p. 104.[6] Hence by transitivity, utterances which are signs of concepts which are signs of things are themselves signs of things: "An utterance that is a sign of a sign ... [is] a sign of the concept directly but a sign of the thing indirectly", tr. Kretzmann and Stump, p. 105.[7] For example, 'man' immediately signifies the concept man, but by mediation of the concept it signifies the second substance or form of man. Accordingly, it can supposit for what fall under man, e.g., Plato and Socrates. But it does not signify Plato or Socrates.

As noted above, this last distinction was elided by Ockham, in removing the universal, the form. ‘Man’, he says, signifies Plato and Socrates and all men equally. Once signification is treated extensionally in this way, its only difference from supposition lies in its priority: a general term signifies all those things of which it can be truly predicated (Ockham, *Summa Logicae* I c. 33).

3. Supposition and Copulation

Just as signification corresponds most closely -- though not exactly -- to contemporary ideas of meaning or sense, so supposition corresponds in some ways to modern notions of reference, denotation and extension. The comparison is far from exact, however. One major difference is that the medievals distinguished many different modes (*modi*) of supposition. Despite the difference between different authors’ semantic theories, particularly as they developed over the centuries, there is a remarkable consistency in the terminology and interrelation of the different modes.

The major division is between material, simple and personal supposition. Material supposition is when a term stands for a linguistic item as such. Often, of course, this will be a case of autonymy, when it stands for itself. William Sherwood writes: "It is called material when a word itself supposits either [A] for the very utterance itself or [B] for the word itself, composed of the utterance and the signification -- as if we were to say [A] ‘man is a monosyllable’ or [B] ‘man is a name’", tr. Kretzmann, p. 107.[8] Writing in Paris nearly a hundred years later, Thomas Maulfelt put it like this: "Material supposition is a term standing for itself or for another similar to it in sound or writing suppositing in the same way or otherwise which it was not imposed to signify or for some other sound which is not inferior to it, and which it does not signify naturally and properly", my translation.[9] ‘Noun’ supposits materially for itself when we say ‘Noun has four letters’ -- or ‘"Noun" has four letters’; it doesn’t supposit materially, but personally for itself, when we say ‘A noun is a part of speech’.

Simple supposition is harder to characterize generally. A common description is to say it occurs when a term supposits for the universal or form which it signifies. However, not everyone believed that terms signified universals. (See the entry on the medieval problem of universals.) So whereas William of Sherwood wrote "It is simple when a word supposits what it signifies for what it signifies", tr. Kretzmann p. 107,[10] and Walter Burleigh likewise: "supposition is simple when a general term or a complex singular term supposits for what it signifies", my translation,[11] William of Ockham appears to characterize simple supposition quite differently: "Simple supposition occurs when a term supposits for an intention of the soul and is not functioning significatively", tr. Loux p. 190.[12] But in fact, the difference between them is not in their theories of supposition, but rather of signification. As we noted earlier, Ockham believes that a general term like ‘man’ signifies individual men like Plato and Socrates; Burleigh that it signifies a second substance (the universal), man. Burleigh appeals to the authority of Aristotle: "man signifies a second substance and does not signify a substance which is a genus, and so signifies a species".[13] Ockham, however, dismissed real universals, and (at least in his later theory represented in *Summa Logicae)* believed the only universals were words, including words of the inner mental language, mental acts. So for him, a spoken or written term has simple supposition when it stands

for the mental act to which it is subordinated by the conventions of signification, that is, the mental act abstracted from those things which the word conventionally signifies.

John Buridan famously eliminated simple supposition altogether, for this very reason, namely, that universals are words of a mental language, so terms suppositing for them are suppositing for a kind of linguistic item, and so such a case should be included under material supposition.

Material and simple supposition are contrasted with personal supposition, what we might call the standard case, where a term stands for ordinary objects -- the objects it signifies (for Ockhamists) or for its supposita, as for example, Lambert (p. 209) or Burleigh express it: "Personal supposition is when a term supposits for its suppositum or supposita or some singular of which the term is [truly and] accidentally predicable".[14] The contrast is a useful one, as is shown in the following standard fallacies:

Homo est dignissima creaturarum	(Man is the worthiest of creatures)
Sortes est homo	(Socrates is a man)
Ergo Sortes est dignissima creaturarum	(So Socrates is the worthiest of creatures).

The premises are true and the conclusion false, so wherein lies the fallacy? It is one of equivocation or "four terms": ‘homo’ (’man’) has simple supposition in the first premise and personal supposition in the second, so there is no unambiguous middle term to unite the premises. Again:

Currens est participium	(Running is a participle)
Sortes est currens	(Socrates is running)
Ergo Sortes est participium	(So Socrates is a participle).

This time, ‘currens’ (’running’) supposits differently in the two premises, materially in the first and personally in the second, explaining why putting the two truths together fallaciously leads to the false conclusion.

What determines whether a term has material, simple or personal supposition? One view might be that it depends on the intention of the speaker; another, that all propositions are ambiguous. However, the prevailing medieval view was that it was determined by the predicate, so that, e.g., a predicate like ‘is a noun’ requires material supposition for the subject, while ‘is a species’ requires simple supposition: "A subject, on the other hand, sometimes supposits a form separately and sometimes does not, depending on what the predicate demands, in accordance with the following [principle]: Subjects are of such sorts as the predicates may have allowed", tr. Kretzmann, p. 113.[15] This slogan, *talia subiecta qualia predicata permiserint* (subjects are such as predicates permit), was commonly attributed to Boethius; but Sherwood correctly points out that Boethius’ point was different, and his phrase was the converse: *"talia [predicata] qualia subiecta permiserint"* -- see De Rijk, *Logica Modernorum* II (1), p. 561.

In the fourteenth and fifteenth centuries, it became commonplace to require a *nota materialitatis* (a sign of the material use) for a term in material supposition. Such a sign was to prefix ‘iste terminus’ (’this term’) or ‘ly’ (taken from the French definite article) to the term. Without such an indication, the term was considered to have personal supposition by default.

Personal supposition is divided by most authors into discrete and common supposition, the first that of singular terms (proper names, demonstrative phrases and so on), the latter that of general terms. Common personal supposition is again divided, namely, into determinate and confused, and the latter into confused and distributive and merely confused supposition. These three modes are well illustrated by the four categorical forms (see the entry on the traditional square of opposition):

> (A) All A are B
>
> (E) No A are B
>
> (I) Some A are B
>
> (O) Some A are not B.

The subject of (I)- and (O)-, and the predicate of (I)-propositions, have determinate supposition; the subject and predicate of (E)-, the subject of (A)-, and the predicate of (O)-propositions have confused and distributive supposition; and the predicate of (A)-propositions has merely confused supposition. This is common doctrine; what varies is how these modes are characterised. "It is determinate", writes William of Sherwood, "when the locution can be expounded by means of some single thing", tr. Kretzmann, p. 108, but adds a doubt: "It seems that when I say ‘a man is running’ [i.e. an I-proposition] the term ‘man’ does not supposit determinately, since [A] the proposition is indefinite, and [B] it is uncertain for whom the term ‘man’ supposits. Therefore it supposits [A] indefinitely and [B] uncertainly; therefore indeterminately", tr. Kretzmann, pp. 115-6.[16] But this is simply a matter of terminology, he replies -- determinate supposition means suppositing for one, not for many, but for no particular one, for that would constitute discrete supposition. Note, however, that for Ockham, Burleigh and others, a term with determinate supposition supposits for everything of which it can be truly predicated. The sense in which it is true of one, rather than many, is that the proposition is true if true of one. The term still supposits for all. As Burleigh says: "It is called determinate supposition, not because a term suppositing determinately supposits for one and not for all, but it is called determinate supposition because for the truth of the proposition in which the general term supposits determinately, it is required that it be true of one determinate suppositum", my translation.[17]

All that William of Sherwood can offer to characterize confused supposition is to say that it is had when a term supposits for many, then resorting to examples for its divisions. Peter of Spain tries harder: "Confused supposition is the acceptance of a general term for many by means of a universal sign", my translation,[18] and confused and distributive when it supposits for all. But this is still unclear, and eventually a solution was found, in the doctrine of ascent and descent. Call the individual things falling

under a general term its "inferiors", and call the singular proposition resulting from a general proposition by replacing a general term (with its qualifier) by a term with discrete supposition for one of its inferiors, one of the proposition's "singulars". Then the inference from a general proposition to one of its singulars is called "descent", the converse inference, "ascent". If descent under a term is valid, or at least is valid without changing the rest of the proposition, it is called "mobile", otherwise "immobile". Walter Burleigh, William of Ockham and their followers could then define the three modes of common personal supposition as follows:

1. An occurrence of a general term in a proposition has determinate supposition when one can descend validly from the proposition to the complete disjunction of its singulars with respect to that term, and conversely can ascend validly from any singular;
2. Otherwise, it is confused, and i) is confused and distributive if one can validly descend from the proposition to the indefinite conjunction of its singulars with respect to that term; otherwise ii) it is merely confused.

In this last case, 2 ii), Ockham noted: "it is possible to descend by way of a proposition with a disjunctive predicate and it is possible to infer the original proposition from any [singular]", tr. Loux, p. 201.[19] Thus the predicate of an A-proposition has merely confused supposition since from 'Every man is an animal' one can validly infer 'Every man is this animal or that animal and so on for all animals', and conversely, from 'Every man is this animal' (were it ever true) one could infer that every man was an animal.

A final complication came at the end of the fourteenth century and subsequently, when it was asked: "Are there only three modes of common personal supposition?" Some answered, 'Yes'; but others distinguished two modes of merely confused supposition, or equivalently distinguished a fourth case, 2 iii), collective supposition, where descent was permissible to a proposition with a conjunctive predicate. The standard example was 'All the apostles of God are 12', which entails 'Matthew and Mark and so on are 12', with a conjunctive subject.

Several recent commentators have asked what the medieval theory of modes of common personal supposition was: was it a theory of inference, of quantification, of truth-conditions, of fallacies, or what? Asking these questions may help us to come to terms with the theory; but if pressed too hard, they are unhelpful. The medievals' theory was none of these things; it was their theoretical basis with which to pose and answer semantic questions.

All modes of supposition so far described fall under what was variously called proper supposition or accidental supposition or, excluding material supposition, formal supposition. Distinct from these were what Peter of Spain called natural supposition, mentioned earlier in the discussion of signification, and what Ockham and others call improper supposition, covering metaphor and other figures of speech.

Moreover, various authors before the fourteenth century, and at least one fourteenth century author, too (namely, Vincent Ferrer) differed a little from what has been said in not attributing supposition to

predicate terms, calling the corresponding property of predicates, "copulation". However, even in the early thirteenth century, this distinction was fading. William of Sherwood makes it clearly: substantive names and pronouns supposit, whereas adjectives, participles and verbs copulate. Many of the divisions of supposition are repeated for copulation, but only the modes of common personal supposition: "every copulating word signifies in adjunction to a substantive and thus is copulated personally ... [and] every copulating word is the name of an accident, but every name of an accident is common; therefore no copulation is discrete", tr. Kretzmann, p. 121.[20] However, even in Lambert and Peter of Spain, there is only an empty nod towards copulation. Lambert notes that properly speaking, supposition attaches to substantives, while copulation is appropriate for adjectival terms. But broadly speaking, he says, supposition belongs to both (*op.cit.*, pp. 208/109). The distinction is clearly unnecessary and useless, and although the term is preserved in, e.g., Walter Burleigh's *De Puritate,* his discussion headed 'On Copulation' is in fact a discussion of the uses of the copula, 'est'.

4. Ampliation and Restriction

Some words have the effect of widening or narrowing the supposition of other terms in a proposition. For example, by qualifying 'man' with the adjective 'white', we restrict the supposition of 'man' in 'A white man is running' to white men; while a verb in the past tense ampliates the supposition of the subject to what were its supposita. For example, 'A white thing was black' means that something which is now white or was white in the past was black.

Lambert of Auxerre describes the many aspects of a proposition which can produce ampliation or restriction. Some are natural, as when 'rational' restricts 'animal' to supposit only for men by being adjoined to it; other cases are '*usualis*' -- 'use-governed' in Kretzmann and Stump's translation: when we say 'The king is coming', we are taken to mean the king of the country where we are, so 'king' is restricted to supposit only for that king. Some ampliation and restriction is effected by consignification, that is, by an aspect of a word -- by the tense of the verb, or by the gender of an adjective: in 'homo est alba', the feminine ending of 'alba' restricts 'homo' to supposit only for women. Other ampliation and restriction is effected by the signification of words -- as in the case of 'rational animal' above, or in 'Socrates' donkey', where the possessive restricts 'donkey' to supposit only for Socrates' donkeys.

Peter of Spain notes that only general terms can be ampliated or restricted, and only terms having personal supposition.

Just as the past tense ampliates the subject to include past as well as present supposita, modal verbs ampliate the subject to possible supposita, as do verbs such as 'I understand', 'I believe', and indeed, notes Albert of Saxony, verbal nouns ending in '-bile': 'possible', 'audible', 'credible', 'capable of laughter' and so on. Albert realises that even 'supposit' ampliates the subject: when we say 'This term supposits for something', what it supposits for need not actually exist, but might be past, future, possible or merely intelligible. Similarly, 'must' ampliates for possible supposita, for 'A must be B' means 'It is not possible that A not be B'; but contradictories must clearly ampliate in the same way, and 'It is possible that A not be B' ampliates for possibilia. Ampliation over possibles means care is needed in

inferences from ‘is’ to ‘can’: ‘A can be B’ need not follow from ‘A is B’, for ‘A can be B’ means that what is or can be A can be B, and even if A is B, not everything which can be A might be capable of being B. For example, ‘Every planet lighting our hemisphere can be the sun’ is false even though it in fact is the sun which lights it, since the moon might light our hemisphere but the moon cannot be the sun.[21]

It is an interesting fact that almost alone among terminist logicians, Ockham does not speak of ampliation and restriction. The reason appears to be that he disagrees with the truth-condition given above for ‘A white thing was black’, and similar cases. This proposition, he says, is ambiguous. Rather than meaning that what is or was white was black, it equivocates between ‘What is white was black’ and ‘What was black was white’: "quaelibet propositio de praeterito et de futuro, in qua subicitur terminus communis vel pronomen demonstrativum cum termino communi vel terminus discretus importans aliquod compositum, est distinguenda", *Summa Logicae* II 7, p. 269 ("in the case of every proposition of the past and of the future in which a general term or a demonstrative pronoun with a general term or a discrete term referring to some composite, we must distinguish [two senses]", my translation). Whether Ockham realized that his theory improved on the ampliative theory is unclear; nonetheless, his account seems to accord better with intuition. For the ampliative account is disjunctive: it says that the proposition is true if either what was white was black or what is white was black. Then it is true if either disjunct is true; whereas on Ockham’s account it has two different senses, and can be false on one while true on the other -- true because something now white used to be black but false if nothing which used to be white was ever black. For a clearer case, take the first sex-change operation -- for the first time, say, a woman was a man. But no one who was a woman had ever been a man, so it was (also) false that a woman was a man. The proposition ‘A woman was a man’ is ambiguous and "*est distinguenda* " (i.e., different senses must be distinguished). A famous example was ‘An old man will be a boy’, referring to someone not yet born -- he will be an old man sometime, and will be a boy before that.

Ockham also eschews talk of ampliation in giving his account of modal propositions. Does ‘A white thing can be black’ mean that what is or can be white can be black, i.e., that either what is white can be black or what can be white can be black, as the ampliative account demands? -- see, e.g., Albert of Saxony: "’A white thing can be black’: this signifies that what is white or what can be white can be black", my translation.[22] No, for this loses the sense in which it is self-contradictory to suggest that it is possible that a white thing be black. The proposition is ambiguous, in one sense self-contradictory, in the other true, Ockham notes (*Summa Logicae* II 10), because ‘This is black’ can be true if uttered pointing to something white: "‘A white thing can be black’ is true, because ‘This is black’ is possible, pointing to something for which ‘white’ supposits; but ‘A white thing is black’ is impossible".[23]

5. Appellation

Perhaps the term with the most varied history is ‘appellatio’, though even so, one can discern a common thread running through it. It starts, we saw, as an equivalent of ‘nominatio’ in Anselm and Abelard, and by the thirteenth century is used to pick out the present extension of a term, that of which it can be truly predicated in the present tense: "Now it is essential to know that ‘appellation’ is used in four ways ...

Used in the fourth way, 'appellation' is the acceptance of a term for a suppositum or for supposita actually existing. And it is appellation spoken of in this fourth way that is meant at present", tr. Kretzmann and Stump, pp. 113-4.[24] In Burleigh, at the turn of the fourteenth century, it almost usurps the place of 'copulatio', being for him the relation of the predicate to its inferiors: "Just as supposition, strictly speaking, is a property of the subject in relation to the predicate, so appellation is a property of the predicate in relation to the subject or to its inferiors", my translation.[25] There are shades too, of Abelard: "a univocal general term appellates its inferiors but does not signify them".[26] But the crucial phrase which runs through the history of the term appears here too: "the predicate appellates its form", *op.cit.*, p. 48 ("praedicatum appellat suam formam"). What he says he means by this is that the predicate be truly predicable at some time, in the present tense, of the supposita of the subject.

It is ampliation and restriction which distinguish this property of the predicate from properties of the subject. For, on the standard account, 'A white thing was black' is true only if 'is black' has been truly predicable of the supposita of the subject, namely, of what is or was white. In contrast, 'A white thing is black' may never have been true -- indeed, in this case, it never will have since it is self-contradictory. So the subject does not always "appellate its form". A consequence pointed out by Albert of Saxony, among others, is that conversion needs application with care in such cases. Consider 'The just will be justly damned': this can be true, if those who are just sin in the future. But 'Justly will the just be damned' is false, for 'Justly are the just damned' will never be true. Similarly, 'Socrates approaching you know' can be true while 'You know Socrates approaching' (the "hooded man" fallacy from Aristotle's *De Sophisticis Elenchis* 179b1-3) may be false (for you know Socrates, but do not recognize him approaching). It is explained by reason of the fact that the predicate appellates its form (for 'You know Socrates approaching' requires that the predicate 'know Socrates approaching' be true of you and so is false), whereas 'Socrates approaching you know' requires only that 'Him you know' be true, referring to Socrates, and it is true. The doctrine of appellation could thus be used to diagnose familiar fallacies.

Scott, in his discussion of Buridan's sophism, 'You know the one approaching' (pp. 42-9), claims that Buridan's concept of appellation (which he misleadingly translates as 'connotation') in his diagnosis is novel, and Spade follows him in his commentary on Peter of Ailly(p.109 n.188). But the notion is clearly continuous with Burleigh's in that 'appellating its form' requires true predication via a demonstration. Indeed, it is continuous with Lambert's usage, for 'chimera' has no appellata precisely because 'hoc est chimera' ('This is a chimera') is false whatever is demonstrated. Admittedly, Buridan explicitly restricts appellation to appellative terms, that is, "every term connoting something other than that for which they supposit" (*Treatise on Suppositions*, tr. King, p. 159), and "it appellates that which it connotes as belonging to that for which it supposits". Thus 'white' connotes whiteness and supposits for white things. What appears to be novel in Buridan is the extension of the doctrine to intentional verbs, which, says Buridan (and Albert) cause the terms following them (the predicate) to appellate their *rationes*, that is, the concepts by which they signify what they do. Thus in 'You know Socrates approaching', the predicate 'know Socrates approaching' appellates its concept, the *ratio* 'Socrates approaching', so the proposition is false unless you are aware who it is; whereas in 'Socrates approaching you know', the subject 'Socrates approaching' does not appellate its concept, and so it suffices that 'Him you know' be true, where 'him' refers to Socrates.

6. Relation

Lambert of Auxerre speaks explicitly of relation as a property of terms, but most authors describe the phenomenon as the supposition of relatives. The relation in question is that between anaphoric terms and their antecedents. Most treatises consist of a repetition of a standard taxonomy: there are relatives of substance and relatives of accident, relatives of identity and relatives of diversity. For example, relatives of substance and of identity are 'who', 'he', 'his', and among these, reciprocal relatives such as 'himself'; of diversity are 'another' and 'someone else'. The latter are said to refer back (*referre*) to their antecedent but to supposit for something different, as in, e.g., 'Socrates is running and someone else is debating'. Relatives of accident include, first, of identity, 'such as', 'like', 'when', and of diversity, 'in another way', 'other'; in, say, 'Socrates is running and Plato is other', 'other' refers back to 'running'; in what way it differs will depend on the author's account of predicates.

In contrast to the extensive taxonomy, medieval discussions of relatives before the mid-fourteenth century seem rather short on theory, dealing with puzzles more by common sense and description than in any unified way. For example, the prevailing view is that relatives of identity preserve the supposition of their antecedent. Why, then, can they usually not replace the antecedent? Consider, e.g., 'Every man sees himself'. Does 'himself' have the same supposition as 'man' (or 'every man') and if so, why can the antecedent not replace it? -- for 'Every man sees every man' has a very different signification. Lambert claims that in the case of reciprocal relatives the reciprocal pronoun can replace the antecedent unless the antecedent is taken universally, as here. In this case, it still supposits for the same as its antecedent, but in a different way, namely, discretely. Ockham spells it out: "in 'Every man sees himself', 'himself' supposits for every man by means of confused and distributive mobile supposition: but it does this singularly since it is not possible to descend without altering the other extreme ... thus, 'Every man sees himself, therefore, Socrates sees Socrates'", tr. Loux, p. 218.[27] This is correct and sensible; but what is the theory to explain it?

Ockham claims that, although non-reciprocal relatives of identity always supposit for that for which their antecedent supposits, those whose antecedent is a general term occurring with personal supposition can never be replaced by their antecedent and result in an equivalent proposition. For example, 'A man runs and he disputes' is not convertible with 'A man runs and a man disputes'. Buridan has two rules to explain what is happening:

1. A relative of identity refers back to its antecedent in respect only of those of its supposita for which the categorical proposition in which its antecedent occurred is verified
2. A relative of identity supposits as its antecedent does, viz materially if materially, personally if personally, distributively if distributively, determinately if determinately, merely confusedly if merely confusedly, except as in 1.

Hence, in e.g., 'Man is a species and it is predicable of many', or 'Socrates runs and he disputes', the relative can be replaced without loss of meaning by its antecedent. But in 'A man runs and he disputes',

it cannot, for the supposition would change. ‘He’ supposits only for men who are running, whereas ‘a man’, if it replaced it, would supposit for all men.

Another issue concerned identifying the contradictory of a proposition containing a relative. In the case of a categorical containing a relative of identity such as ‘A which is B is C’, it is ‘A which is B is not C’, says Albert of Saxony (*Perutilis Logica* II 8, f. 14rb, ed. Muñoz García §§526-7). For the former is equivalent to ‘A is B and A is C’, and the latter to ‘A is not B or A is not C’, he says.

7. Conclusion

The medievals did not have a solution to every semantic puzzle with which they were faced, any more than do contemporary philosophers. But the theory of properties of terms was the basis of a rich semantic theory within which they were able to develop complete and fruitful theories which yielded significant insights -- both for them and for us -- into a broad range of semantic issues.

Notes to Medieval Theories of Properties of Terms

Notes

1. "Quattuor sunt proprietates termini quas ad presens intendimus diversificare ... Et sunt hes proprietates significatio, suppositio, copulatio et appellatio", *Introductiones in Logicam*, pp. 74-5.

2. "Multa autem sunt proprietates termini, scilicet: suppositio, appellatio, restrictio, distributio [ed.: distinctio] et relatio ... sed quia significatio est sicut perfectio termini et proprietates termini supra significationem fundantur, ideo in principio ad evidentiam sequentium videndum est quid sit termini significatio et in quo differt a suppositione", *Logica Lamberti*, p. 205.

3. "manente significatione variata nominis suppositio", edited in De Rijk's *Logica Modernorum*, vol. I p. 562, and in the *Tractatus de univocatione monacensis* as "manente eadem significatione variata nominis appellatio", *op.cit.* vol. II(2) p. 337.

4. "Differt autem significatio a suppositione in hoc, quod prior est significatio quam suppositio", *Logica Lamberti*, p. 206.

5. "quaerit Alexander si rerum nomina sunt, quid causae est ut primo intellectuum notas esse voces dixerit Aristoteles ... inquit, quod licet voces rerum nomina sint, tamen non idcirco utimur vocibus, ut res significemus, sed ut eas quae nobis ex rebus innatae sunt animae passiones. Quocirca propter quorum significantiam voces ipsae proferuntur, recte eorum primo esse dixit notas", *Patrologia Latina*, vol. 64 col. 413A.

6. "significatio termini est intellectus rei ad quem intellectum rei vox imponitur ad voluntatem instituentis: nam, sicut vult Aristotles in primo Perihermeneias, voces sunt signa passiones que sunt in anima, id est in intellectu; intellectus autem sunt signa rerum", *Logica Lamberti*, p. 205.

7. "vox que est signum signi ... immediate est signum intellectus, mediate autem signum rei", *ibid.* p. 206.

8. "et dicitur materialis, quando ipsa dictio supponit vel pro ipsa voce absoluta vel pro ipsa dictione composita ex voce et significatione, ut sic dicamus: homo est dissillabum, homo est nomen", *Introductiones in Logicam*, p. 75.

9. "Suppositio materialis est terminus stans pro se vel pro alio sibi simili in voce vel in scripto eodem

modo vel aliter supponente cui non imponitur ad significandum vel pro aliqua alia voce que non est inferior ad ipsum, nec ipsum proprie naturaliter significat", *De Suppositionibus*, f. 62r.

10. "Et est simplex, quando dictio supponit significatum pro significato", p. 75.

11. "suppositio vero simplex est, quando terminus communis vel singulare aggregatum supponit pro eo quod significat", *De Puritate*, p. 3.

12. "Suppositio simplex est quando terminus supponit pro intentione animae, sed non tenetur significative", *Summa Logicae*, p. 196.

13. "homo significat secundam substantiam et non significat substantiam quae est genus, ergo significat speciem", p. 7.

14. "Suppositio personalis est, quando terminus supponit pro supposito vel suppositis vel aliquo singulari, de quo terminus accidentaliter praedicatur", *De Puritate*, p. 3.

15. "Subiectum autem quandoque supponit formam absolute, quandoque autem non et hoc secundum exigentiam predicati secundum illud: talia sunt subiecta, qualia permiserint predicata", Sherwood, *Introductiones in Logicam* p. 78.

16. "Et est determinata quando potest exponi loqutio per aliquod unum", p. 75; "Videtur enim, quod iste terminus homo, cum dico: homo currit non supponit determinate. Est enim indefinita. Et item incertum est, pro quo supponit. Ergo supponit incerte et indefinite. Ergo indeterminate", p. 79.

17. "Et dicitur suppositio determinata, non quia terminus sic supponens determinate supponit pro uno et non pro alio, sed dicitur suppositio determinata, quia ad veritatem propositionis, in qua terminus communis supponit determinate, requiritur quod verificetur pro aliquo supposito determinato", *De Puritate*, p. 20.

18. "Confusa suppositio est acceptio termini communis pro pluribus mediante signo universali", *Tractatus*, pp. 82-3.

19. "[contingit descendere] per propositionem de disiuncto praedicato, et contingit eam inferri ex quocumque singulari", *Summa Logicae* p. 211.

20. "quia omne copulans significat in adiacentia ad substantiam et sic copulatur personaliter. Item omne copulans est nomen accidentis. Sed omne nomen accidentis est commune. Ergo nulla copulatio est discreta", p. 81.

21. Remember that ‘planet’ included the Sun and the Moon in the middle ages, that is, any heavenly body with an irregular motion.

22. "’album potest esse nigrum’; ista significat quod illud quod est album, vel potest esse album, potest esse nigrum", *Perutilis Logica* II 10 f. 15va, ed. Muñoz García §581.

23. "haec est vera ‘album potest esse nigrum’, quia haec est possibilis ‘hoc est nigrum’, demonstrando aliquid pro quo ‘album’ supponit; et tamen haec est impossibilis ‘album est nigrum’", p. 278.

24. "Sciendum autem quod appellatio dicitur quatuor modis ... Quarto modo dicitur appellatio acceptio termini pro supposito vel pro suppositis actu existentibus, et de appellatione isto quarto modo dicta est presens intentio", *Logica Lamberti*, pp. 211-2.

25. "Unde sicut suppositio stricte accepta est proprietas subiecti, prout comparatur ad praedicatum, ita appellatio est proprietas praedicati comparati ad subiectum sive ad inferius", *De Puritate*, p. 47.

26. "terminus communis univocus appellat sua inferiora sed non significat sua inferiora", *loc.cit.*

27. "in ista ‘omnis homo videt se’ li se supponit pro omni homine confuse et distributive immobiliter et singillatim, quia non contingit descendere non variando aliud extremum ... sic dicendo ‘omnis homo videt se, igitur Sortes videt Sortem’", *Summa Logicae* I 76, p. 235.

A Proof Concerning Bradwardine's Theory

Here is a proof that on Bradwardine's theory, every proposition signifies that it is true. Let ‘P’ name the proposition replacing *’p.’* Then:

1. *p*	Assume for conditional proof.
2. P signifies that *q*	Assume for conditional proof.
3. $p \rightarrow q$	From 2 and the thesis that what propositions signify follows from them.
4. *q*	From 1, 3, and *modus ponens*
5. (P signifies that *q*) $\rightarrow q$	From 2-4, by conditional proof.
6. P is true.	From 5 and Bradwardine's definition of truth, since 5 is general with respect to propositions replacing ‘*q*’.
7. $p \rightarrow$ P is true	From 1-6, by conditional proof.
8. P signifies that P is true.	From 7 and "Bradwardine's Principle."

Nicholas of Autrecourt [de Altricuria; Autricuria, Ultricuria; Autricort]

The most striking feature of Autrecourt's academic career is his condemnation in 1347. In almost every history of medieval philosophy, his censure is presented as one of the most important events in fourteenth-century Paris. In the older literature, Autrecourt's views have become linked to allegedly skeptical tendencies in scholastic thought, and have been unduly shadowed by assumptions about their relation to the views of William of Ockham. Over the last two decades, however, it has become apparent that the study of Autrecourt's thought has been wrongly placed in the larger context of the battle against Ockhamism at the University of Paris in the years 1339-1347. Although Autrecourt was no skeptic -- on the contrary, he attacked the "Academics" or ancient Skeptics -- his philosophical stance challenges the prevailing Aristotelian tradition. In particular, Autrecourt rejected some of the main tenets of scholastic metaphysics and epistemology, such as the substance-accident structure of reality and the principle of causality.

1. Life

As is the case with many medieval thinkers, Autrecourt's biographical details are few. What we know about his intellectual life has to be reconstructed using dates that are attached to the handful of documents in which he is mentioned. One of these is a record from sometime between 1333-36,

indicating that he served as prior at the Collège de Sorbonne. Another important document is a papal letter of 1338 in which Benedict XII confers upon him the function of canon at Metz Cathedral, and refers to him as a master of arts and bachelor of theology and civil law. Evidently, however, Autrecourt did not claim his prebendary stipend until after his trial in 1347.

On the basis of such references, Autrecourt's date of birth can be placed sometime between 1295-98. He originated from Autrécourt in the diocese of Verdun, and was probably a student in the arts faculty at Paris, belonging to either the English, or, more likely, the French nation. His master's degree in arts can be dated around 1318-20. While a student, he must have come across such famous masters as John of Jandun, Marsilius of Padua, Thomas Wilton, Walter Burley, Bartholomew of Bruges, or Siger of Courtrai. Since his law degree was in civil rather than canon law, he must have left Paris at some point for a minimum of five years, probably to study at Orléans, Avignon, or Montpellier.

His membership in the Collège de Sorbonne places Autrecourt back in Paris in the 1330s as a student of theology. On November 21, 1340, Pope Benedict XII summoned him from Paris to Avignon to respond to allegations of false teaching. In his letter, the pope refers to Autrecourt as a *licentiatus* in theology, meaning that Autrecourt had fullfilled the formal requirements for the theology degree, e.g., lecturing on the Bible and the *Sentences*. But does it also mean that he was a full-fledged master of theology? The question is controversial. In the judgment at his trial, it was stipulated that Autrecourt could only obtain "magisterial honor and degree" after special permission from the Apostolic See, which seems to imply that he was not allowed to progress to inception in theology (the ceremony in which the magisterial honors would be conferred) until the pope decided otherwise. Moreover, there are no records referring to Autrecourt as a master in theology. This suggests that Autrecourt remained a *licentiatus* in theology when he moved on to Metz to take his position as canon (and later dean) of the cathedral chapter. He died in 1369, on either July 16 or 17.

2. Autrecourt's Trial and Conviction

Autrecourt's time of trial began in 1340 when he was first summoned to appear before the papal court in Avignon and lasted until his conviction in 1346. An extensive, though as yet incomplete, dossier of the judicial process at Avignon has been preserved in the form of an *instrumentum publicum* (actually, a draft copy thereof), which served as a model for the preparation of the official record of the process. The papal dossier contains copies of a number of records that played a role during earlier stages of Autrecourt's trial, and gives an account (*narratio*) of the judicial proceedings from the moment Cardinal Curti, the judge, took over the investigation.

The record specifies the charges and summarizes the false teachings of which Autrecourt was accused in the form of four lists, together totalling 66 erroneous propositions or "articles" (*articuli)*. The articles were culled from Autrecourt's writings and oral teachings. On the basis of this record, it would appear that the papal commissions of Pope Clement VI and Cardinal Curti used evidence from earlier proceedings at the University of Paris and Autrecourt's response to this evidence to reach their verdicts. If this scenario is correct, it raises two obvious questions: why was Autrecourt's trial transferred from

Paris to Avignon, and how did it begin in the first place? Unfortunately, the surviving historical evidence is insufficient to answer either question.

The commission of prelates and theologians, which under the chairmanship of Cardinal Curti had discussed all of the articles attributed to Autrecourt, came to the conclusion that they contained many false, dangerous, presumptuous, suspect, erroneous, and heretical statements. For this reason, Autrecourt's writings were ordered burned either at Pré-aux-Clercs or Pré-de-Saint-Germain at Paris at an unspecified future date. Moreover, Autrecourt was ordered to publicly recant several of the articles specified in the legal record. These recantations and declarations, which Autrecourt was first required to make at the palace of Cardinal Curti in Avignon, had to be repeated at the University of Paris. Autrecourt's recantation at the papal court took place before May 19, 1346. The exact date is unknown because it was left blank in the draft prepared by the notary Bernard. In addition to the recantation, Autrecourt was declared unworthy to ascend to the magisterial rank in the theological faculty. Anyone in possession of the authority to present or promote Autrecourt to the magisterium of the faculty of theology was thereafter forbidden to do so.

The Parisian part of the sentence was fulfilled the following year. On November, 20, 1347 the regent and non-regent masters of the university met at the Church of Saint-Mathurin, where papal letters and the process "concering certain articles" were read. This material had been brought from Avignon by Autrecourt himself. On November 25, Autrecourt recanted the four confessed articles and the articles from the letter "*Ve michi*" in the Church of the Dominicans, and publicly declared that the propositions contained in the other two lists were wrong. In addition, he burned these articles and a treatise, most likely the *Exigit ordo*. The public reading of the *instrumentum* and the recantation served an important purpose. It not only made the sentence effective, but also informed the scholarly community of Autrecourt's errors and of the punishments set out in the *instrumentum*, which they would incur if they were to teach the censured errors. Years later, scholars such as John Buridan, Marsilius of Inghen, and André of Neufchâteau (Andreas de Novo Castro) cited the condemned erroneous propositions as the *articuli cardinalis (albi)*.

3. Writings

Autrecourt's oeuvre is not large. There is a correspondence with the Franciscan theologian Bernard of Arezzo, and with a certain master Giles (possibly Giles of Feno), and a treatise that has come to be known as the *Exigit ordo*. Furthermore, we have a theological question dealing with the intension and remission of forms and the problem of minima and maxima (*utrum visio alicuius rei naturalis possit naturali intendi* [Could the vision of any natural thing be naturally intensified?]).

Autrecourt wrote nine letters to Bernard of Arezzo, only two of which survive. In addition, there is one letter from master Giles addressed to Autrecourt, along with a brief response by the latter, which, however, breaks off in mid-sentence. The correspondence has been preserved in two manuscript copies from the intellectual milieu of the Collège de Sorbonne. Together the letters form a small dossier, the central item of which is the letter from Master Giles. Apparently, the only reason the two letters to

Bernard were copied was because they are mentioned in the letter from Master Giles. The correspondence between Autrecourt and Bernard of Arezzo is much earlier, dating from the time when both were theology students, engaged as opponents in each other's *Principia*, i.e., inaugural lecture on the *Sentences*. They can be dated between October 1335 and June 1336, although both *Principia* are now lost. There is no evidence that Autrecourt ever actually wrote a commentary on the *Sentences*, which, in any case was not a formal requirement for obtaining a degree. The theme of the discussion in the *Principia* and the letters to Bernard of Arezzo is the validity of Aristotle's principle of non-contradiction, as presented in Book IV of the *Metaphysics*.

The *Exigit ordo* is the fruit of Autrecourt's teaching in the arts faculty. Instead of expounding his views in commentaries on Aristotle's texts, Autrecourt chose to write an independent treatise discussing issues pertaining to natural philosophy, metaphysics, epistemology, philosophical psychology, and ethics, and engaging in debate with unnamed contemporaries. The work was completed in the years 1333-35, at which time Autrecourt was preparing his commentary on the *Sentences*. For financial reasons, Autrecourt taught in the arts faculty while he was enrolled as a student in theology.

The *Exigit ordo* is also known as the *Tractatus universalis* (Universal Treatise). The latter title is actually a misreading of the first two words of the treatise, "*tractatus utilis*" (useful treatise). It has been preserved in a single manuscript copy, which, like the Giles letter, breaks off in mid-sentence. It is divided into two prologues, two treatises, and several chapters, which, unfortunately, the scribe has placed in the wrong order. The Latin edition and English translation both preserve the order of the medieval manuscript without correction.

The theological question is a report (*reportatio*) of a theological disputation in which Autrecourt served as respondent to the objections. Although the presiding master of a disputation would usually have to be considered its real author, matters may be different here. Since it is a *reportatio* -- i.e., a text which, unlike an *ordinatio*, was not subjected to later editing by the master himself -- Autrecourt's views probably appear in unadulterated form. The question was disputed between 1336-1339, and has been little studied by scholars.

4. Epistemology

Central to Autrecourt's teaching is the view that all *evident* knowledge (with the exception of the certitude of faith) must be reducible to the first principle (*primum principium*), i.e., to the principle of non-contradiction. An inference yields evident knowledge only when the affirmation of its antecedent and the negation of its consquent are contradictory. This means that the antecedent and the consequent, or, more precisely, what is signified by the antecedent and the consequent, must be identical, "because if this were not the case, it would not be immediately evident that the antecedent and the opposite of the consquent cannot stand together without contradiction." It is in the context of this theory that Autrecourt launches an attack on our claim to have certain knowledge of the existence of substances and causal relations. If A and B are two distinct entities, he says, one cannot infer with certainty (knowledge of) the existence of A from that of B or vice versa, for the affirmation of the one and the denial of the other does

not result in a contradiction. On the basis of this principle, one may not infer (knowledge of) the existence of effects from knowledge of their causes, nor (knowledge of) the existence of substances from knowledge of their accidents.

This view runs contrary to the Aristotelian position, according to which causal relations really exist and are discoverable by means of induction, so that the existence of substances can be inferred from the perceptible accidents inhering in them. The upshot of Autrecourt's view is that we do not have experience of causal relations or substances, nor does logic provide certain knowledge of them. There are no logical reasons to assume that there is an evident relation between a cause and an effect, or between a substance and an accident.

The position outlined above is developed in Autrecourt's correspondence. It has led historians of philosophy to characterize him as the most important, if not the only, "real" representative of medieval scepticism, as "the medieval Hume", to use Hastings Rashdall's epithet. On closer inspection, however, it turns out that Autrecourt's scepticism is reserved for rationalist claims about the truth of our commitments to causality and substance, concepts for which we have no empirical proof. He is not a sceptic at all when it comes to defending the reliability of sense-perception.

In his *Letter to Bernard*, Autrecourt takes on Bernard of Arezzo, who had argued that the intellect is neither certain of the existence of those things of which it has a clear intuitive cognition, nor of its own acts. Autrecourt reveals the full implications of this position by pointing out to Bernard that "you are not certain of those things which are outside of you. And so you do not know if you are in the sky or on earth, in fire or in water...Similarly, you do not know what things exist in your immediate surroundings, such as whether you have a head, a beard, hair, and the like." He concludes that Bernard's stance is even worse than that of "the Academics," that is, the ancient Skeptics.

5. Metaphysics

To Bernard's skeptical challenges Autrecourt replies that sense experience is reliable. This theme is not further developed in the letters to Bernard, however. For discussion of this topic we must turn to the *Exigit ordo*. In one section of this treatise, which is reminiscent of Aristotle's *Metaphysics* IV, 5, Autrecourt addresses one of the central issues of metaphysics, namely the relation between appearance and reality. He addresses Protagoras' view that whatever is apparent is true: *An omne illud quod apparet sit*? (Does everything that appears exist?).

Autrecourt defends the thesis that what appears, is, and that what appears true, is true. He finds this view more plausible than its opposite, viz., that the intellect cannot possess certitude. His concept of appearance plays a key role in his doctrine of certain knowledge. It is used in a phenomenological sense, to describe perceptual experiences. According to Autrecourt, the intellect is certain of everything that is evident to it in the final analysis. This is the case for everything that appears in a proper sense (*apparet proprie*), i.e., that appears clearly in an act of the external senses *(in actu sensuum exteriorum*). He identifies appearances with the objects of immediate sensory experience, which are considered evident.

In this way, he implies that sense perception is a reliable source of truth, i.e., that the apparent properties of an object are its actual properties.

But is sense perception reliable? Perceptual errors and dreams seem to indicate that things are not always as they seem. Autrecourt discusses several sceptical doubts (*dubia*), versions of what would later be called the "argument from illusion" and the "argument from dreaming". These arguments work from the common sense assumption that things often appear to be other than they are: e.g., sweet food can appear bitter, a white object can appear red, in sleep it can seem to someone that he is flying through the air or fighting the Saracens. How does Autrecourt respond to these sceptical doubts?

By distinguishing between appearance and judgment. Appearances are always veridical: experience cannot be other than it is. However, judgments made from experience can be erroneous, especially if they are based on images rather than on what is perceived "in the full light." In other words, Autrecourt denies any conflict of appearances. Those not "in the full light" are not in themselves misperceptions because the experiences themselves are not illusory. They merely fail to give us the real properties of the object perceived. Potential conflict creeps in at the level of judgment, where ontological claims are made on the basis of appearances. Only those appearances that are "in the full light" reveal the true properties of the perceived object, and only they can provide the basis for true judgments. Appearances of objects that do not come to the perceiver "in the full light" are incomplete or contaminated, as if the observer were looking into a mirror. In other words, Autrecourt carefully distinguishes between ‘x appears F’ from ‘x is F’, for even if x is not really F, it can still appear F and cause someone to believe that it is F. In this way, illusions and dreams turn into mistaken beliefs. Only clear appearances (*apparentiae clarae*) can cause veridical judgments.

A final topic taken up by Autrecourt in this context is the problem of the criterion: How can one discriminate between appearances that provide the basis for true judgments and those that do not? Like Aristotle, he holds that appearances from what we perceive under "normal" conditions cause true judgments. Also like Aristotle, he asserts that there is no further proof that the criterion on which the distinction between veridical and false judgments rests is correct. Both dismiss worries about the justification of the criterion as absurd. In the words of Autrecourt: "One must accept as true what appears in the full light. Now, concerning the minor premise of this argument, how can you have certainty? ... One way of answering this would be to say that there is no way of proving the conclusion, but that the concept of certitude which is present comes as a certain natural consequence, and not as a conclusion. An example, among others, is that white and black are different. This concept of their difference is not gotten by way of conclusion."

6. Natural Philosophy

The point of departure for Autrecourt’s physics is a thesis which strikes him as more probable than what he finds in Aristotle’s *Physics*, namely that all things are eternal. One of the implications of this thesis is that there is no generation or corruption in the universe, which seems to conflict with the way in which properties begin and cease to exist in their subjects, e.g., when something white turns black, so that the

whiteness no longer exists.

According to Autrecourt, no genuine corruption has taken place. It is just that the natural form is no longer visible, since it has been dispersed and divided into its smallest units. In other words, Autrecourt attributes the apparent generation and corruption of things to the motions of atoms. In keeping with this atomistic view, he also holds that space and time consist of indivisible units, viz., points and instants, respectively.

This atomistic explanation of generation and corruption only holds true, he states, if motion is not distinct from the mobile object. For if motion were another distinct thing, it would constitute the generation of something new, whereas rest (the destruction of motion) would constitute its corruption. When seen from this perspective, local motion would refute the eternity of the universe. For this reason, Autrecourt finds it necessary to examine more closely the ontological status of motion.

Autrecourt argues that motion is not a thing distinct from the moving object. Following Ockham, he rejects the idea that motion is a positive thing inhering in the mobile object. Thus, the loss of motion should not be described as the destruction or corruption of an entity, and the eternity doctrine is saved.

7. Semantics

Autrecourt did not leave any logical writings, nor does he discuss logic or semantics in the *Exigit ordo* or in his correspondence. However, from his theological question and a few of the censured articles it is clear that he was familiar with the logical debates of his time. According to one of the articles, Autrecourt claimed that the proposition "Man is an animal" is not necessary according to the faith, because in that sense one does not attend to the necessary connection between its terms. The article should be seen against the background of the sophism "Man is an animal", which received considerable attention in the thirteenth and fourteenth centuries. It served to clarify the relation between meaning (*significatio*) and reference (*suppositio*) by investigating the verification of propositions concerning empty classes. Would the proposition "Man is an animal" still be true if no man exists?

Five other articles that turn up in Autreourt's condemnation concern the *complexe significabile*, or what is signified by an entire proposition. According to adherents of the doctrine such as Adam Wodeham and Gregory of Rimini, the object of knowledge is not the proposition, or the things (*res*) referred to in the external world, but "that which is signified" by the proposition (*complexe significabile*). One of the problems raised by this theory concerned the ontological status of the *complexe significabile*: Is it something (*aliquid*) or nothing (*nihil)*? Echos of this and other debates can be found in these articles.

Peter of Spain (Petrus Hispanus)

Peter of Spain (thirteenth century), exact identity unknown, was the author of a standard textbook on logic, the *Tractatus* (Tracts),[1] which enjoyed a high renown in Europe for many centuries. His works on logic are typical examples of the type of manuals that gradually started to emerge within the context of twelfth- and thirteenth-century teaching practices. Until recently he was also identified as the author of a number of extant works on medicine.

Life and works: Some Comments on the Historiography

Peter of Spain has been established as the medieval author of a work that became widely known as *Summule logicales magistri Petri Hispani* (Collection of Logic Matters of Master Peter of Spain). The great number of manuscripts and printed editions is evidence of the enormous success this work met with throughout European universities well into the seventeenth century. But finding out the true identity of the author of this influential *Tractatus* has proved to be a difficult task. For a long time it was assumed that he was a Portuguese who became Pope in 1276, under the name of John XXI. There is also another, earlier tradition, according to which the author of the *Tractatus* was regarded as Spanish, and a member of the Dominican order. Yet another attribution, dating from the fifteenth century, was to a Petrus Ferrandi Hispanus (d. between 1254 and 1259), which would be consistent with the idea that the work originated from the first half of the thirteenth century. According to still another attribution, the *Summule* was compiled by a Black Friar no earlier than in the late thirteenth or early fourteenth century.

The ‘Dominican-thesis’ can be divided into three traditions:

1. The general view that Peter of Spain, author of the *Tractatus*, is someone who belonged to Order of Black Friars,
2. The more specific view that the author of the *Tractatus* was a frater Petrus Alfonsi Hispanus O.P.,
3. Another specific view that the Peter of Spain who created the *Tractatus* was the same Peter of Spain as the one who wrote the *Legenda sancti Dominici* and the Office of the Saint's Feast, namely Petrus Ferrandi Hispanus O.P., who died in the 1250's.

Current research on the identity of Peter of Spain has once again taken up the idea that he must have been a member of the Dominican Order instead of Pope John XXI.[2] However, we are still in the dark about the true identity of Peter of Spain. The most recent information we have on this score is that four of the Dominican candidates recently suggested as the author of the *Tractatus* can be deleted from the list.[3] The lack of further information also makes it difficult to establish the dates and specifics of his carreer.

The work that has enjoyed such enormous success, the *Tractatus*, is believed to have been written between 1230 and 1245 and has universally been recognised as a work by Peter of Spain. Another work that has been identified as Peter of Spain's is a *Syncategoreumata* (Treatise on Syncategorematic Words), probably written sometime between 1235 and 1245.[4] Considering the fact that in all the thirteenth-century manuscripts the *Syncategoreumata* directly follow the *Tractatus*, and the number of similarities between doctrinal aspects of these two works on logic, it is almost certain that they were written by the same author. Both works seem to have originated from Southern France or Northern Spain, the region where we also find the earliest commentaries on these treatises.

Besides these works on logic, there are other works that have been written by a Peter of Spain. In the *Petrus Hispanus papa* tradition, he is the supposed author of a famous medical work *Thesaurus pauperum*, as well as fourteen other works on medicine. Other works written by (a) Peter of Spain are a *Scientia libri de anima*, and commentaries on Aristotle's *De anima*, *De morte et vita* and *De sensu et sensato*, and commentaries on works by pseudo-Denys the Areopagite. As yet there is no certainty about whether the Peter of Spain who wrote these works is the author of the *Tractatus* and the *Syncategoreumata*, or about the dates of their origin.

Another Peter of Spain, referred to as *Petrus Hispanus non-papa*, has been identified as the author of the *Summa ‘Absoluta cuiuslibet’*, a late twelfth-century handbook on syntax closely linked with Priscian's *Institutiones grammatice, libb.* XVII and XVIII, which became very popular later in the Middle Ages under the name *Priscianus minor*.[5] The chronology of this work seems to rule out that this Peter of Spain is the same author as the author of the *Tractatus*.

Origins of Peter's Works on Logic

Peter's logic has its origin in the continental tradition. The educational carreer of the *Tractatus* appears

from two commentaries,[6] which contain short lemmata and a number of questions (*questiones*) together with their solutions. The tracts as contained in these texts are very similar to the the ones in the *Tractatus*. Typical of the Paris tradition is the separate treatment of ampliation, restriction and distribution, and several other, doctrinal features.[7] Peter's Masters include Johannes Pagus (who is supposed to have been a Master of Arts in Paris in the 1220's) and Hervaeus Brito (who may have been a Master of Arts either before 1229, but possibly later, in which case he does not qualify as a teacher of Peter's). Besides these direct influences, the sources for Peter's works on logic can be traced back to Boethian-Aristotelian logic, and authorities in the field of grammar such as Priscian and Donatus.

Like the *Tractatus*, the *Syncategoreumata* also displays a continental origin, and appears to have continued along the lines of a similar work by Johannes Pagus (which has been dated between 1225 and 1235), later on further developed by Nicholas of Paris (who wrote his *Syncategoreumata* between 1240 and 1250).[8]

The *Tractatus*

The *Tractatus* can be divided into two main parts. One part deals with doctrines found in the so-called *logica antiquorum* -- i.e. the *logica vetus* (old logic) and *logica nova* (new logic) -- and the other contains doctrines covered by the *logica modernorum* -- viz. the tracts that discuss the *proprietates terminorum* (properties of terms).

The first main part of the *Tractatus* divides into five tracts. The first tract, *De introductionibus* (On introductory topics) explains the concepts used in traditional logic -- *nomen* (noun), *verbum* (verb), *oratio* (phrase), *propositio* (proposition) -- and presents the divisions of and the (logical) relationships between propositions. The second tract, *De predicabilibus* (On the predicables) covers matters dealt with in Boethius's accounts of Porphyry's *Isagoge*. It gives an account of the concept *predicabile* and the five predicables -- *genus*, *species*, *differentia*, *proprium*, *accidens* -- i.e., the common features of and differences between the predicables, as well as of the terms '*predicatio*' and '*denominativum*'. Tract three, *De predicamentis* (On the categories), discusses the ten Aristotelian categories, as well as some items already dealt with in the previous treatise. The fourth tract, *De sillogismis* (On syllogisms) mainly goes back to Boethius's *De syllogismis categoricis* (On categorical syllogisms). It gives an explanation of the basic element of the syllogism, i.e. *propositio*, and of the syllogism, and then goes into mood and figure, the proper forms of syllogisms, and briefly deals with what are called paralogisms. The fifth tract, *De locis* (On topical relationships), is derived from Boethius's *De topicis differentiis* (On different topical relationships) I and II. This tract starts off with an explanation of the notions *argumentum* and *argumentatio*, and then proceeds to deal with the species of argumentation: syllogism, induction, enthymeme, and example. Next, it gives a definition of *locus* (the Latin translation of the Greek *topos*): a *locus* is the seat of an argument (i.e., the *locus* is supposed to warrant the inference by bringing it under some generic rule.) The intrinsic *loci* (= the kind of *locus* that occurs when the argument is derived from the substance of the thing involved) are covered first, followed by the extrinsic *loci* (= the kind of *locus* that occurs when the argument is derived from something that is completely separate from the substance of the thing involved) and intermediary *loci* (= the kind of *locus* that occurs when the argument is taken

from the things that partly share in the terms of the problem and partly differ from it). Examples are: intrinsic -- the *locus* "from definition": ‘a rational animal is running; therefore a man is running’; extrinsic -- the *locus* "from opposites": ‘Socrates is black; therefore he is not white’; intermediary -- ‘the just is good; therefore justice is good’.

The second part of the *Tractatus* comprises subjects that were of major importance in the doctrine of the properties of terms. In the sixth tract, *De suppositionibus*, the theory of supposition is dealt with. The treatise begins with an exposition of *significatio*. The definition of *significatio* runs: *significatio* is the respresentation of a thing by means of a word in accordance with convention. Next it gives a definition of the related terms *suppositio* and *copulatio*, and the differences between the terms *significatio*, *suppositio* and *copulatio*. Of these three *suppositio* and *significatio* are the most important in Peter's semantics. *Suppositio* is defined as the acceptance of a substantive verb for some thing. *Suppositio* is dependent on *significatio,* because supposition can only occur via a term that already has some *significatio*. Put in other words, *significatio* pertains to a word by itself, and *supposition* to a term as actually used in some context.

The tract concludes with a division of *suppositio*. The first division is into *suppositio communis* (common supposition) and *suppositio discreta* (discrete supposition) -- e.g. the terms *homo* (man) and *Sortes* (Socrates) respectively.

The second division, *suppositio communis,* is divided into *naturalis* (natural) and *accidentalis* (coincidental). *Suppositio naturalis* is described as the acceptance of a common term for all those things that can share in the common universal nature signified by the term in question -- e.g. *homo* (‘man’) taken by itself by its very nature is able to stand for all men, whether in the past, present or future; *suppositio accidentalis* is the acceptance of a common term for those things for which the term in question requires an additional term -- e.g. in *homo est* (‘A man is’) the term *homo* stands for present men, whereas in *homo fuit* (‘A man has been’) and in *homo erit* (‘A man will be’) it stands for past men and future men respectively, owing to the additional terms *fuit* and *erit*.

The third division, *suppositio accidentalis,* is divided into *suppositio simplex* (simple supposition) and *suppositio personalis* (personal supposition). *Suppositio simplex* is the acceptance of a term for the universal ‘thing’ it signifies, as in *homo est species* (‘Man is a species’, *animal est genus* (‘Animal is a genus’), in which the substantive terms *homo* and *animal* stand for the universal man and animal, and not any one of their particulars. *Suppositio simplex* can occur both in the subject- and in the predicate-term -- e.g. *homo est species* (‘Man is a species’) and *omnis homo est animal* (‘Every man is an animal’) respectively. *Suppositio personalis* is the acceptance of a common term for one or more of its particulars, as in *homo currit* (‘A man is running’).

The fourth division, *suppositio personalis,* is subdivided into either *derterminata* (determinate = standing for a certain particular) or *confusa* (confused = standing for any individual falling under that name). *Suppositio determinata* occurs when a common term is taken indefinitely or in combination with a particular sign -- e.g. *homo currit* (‘Man is running’) or *aliquis homo currit* (‘A /some man is running’). *Suppositio confusa* occurs when a common term is taken in combination with a universal sign (’Every man is running’).

The tract on supposition winds up with the discussion of a few questions regarding the attribution of supposition in a few cases.

The seventh tract of the *Tractatus*, on fallacies, which forms part of the Aristotelian-Boethian logic, is written in the tradition of the *Fallacie maiores* (Major fallacies). The eighth tract, *De relativis* (On relatives) deals with the relative pronouns as defined by Priscian in his *Institutiones grammaticae*. The relative pronouns are devided into: relatives of substance, such as *qui* (who), *ille* (he), *alius* (another), and relatives of accident, such as *talis* (of such a kind), *qualis* (of what kind), *tantus* (so much), *quantus* (how much). The former are subdivided into relatives of identity (*qui* and *ille*) and relatives of diversity (such as *alter* and *reliquus*, both of which can be translated as ‘the other’). The relative of identity is defined in terms of supposition as what refers to and stands for the same thing. These relatives are either reciprocal or non-reciprocal. With regard to the relatives of identity, Peter adds a dicussion of a number of questions about the rationale for using demonstrative pronouns, and some problems concerning how the fallacy of a relative having two diverse referents comes about.

The tract on relatives continues with a brief discussion on the relatives of diversity, accompanied by a rule about the supposition of the relative when it is added to a superior and an inferior in a premiss and a conclusion, as in *aliud ab animali*; *ergo aliud ab homine* (‘Something other than an animal; therefore something other than a man’). With regard to relatives of identity a rule of the "ancients", who deny that a proposition introduced by a relative can have a contradictory opposite, is discussed and rejected. Another rule is given about the identity of supposition of a non-reciprocal relative and what it refers to. The tract concludes with short accounts of relatives of accident.

The ninth, tenth, eleventh, and twelfth tracts of the *Tractatus*, i.e. the short tracts *De ampliationibus* (On ampliation), *De appellationibus* (On appellation), *De restrictionibus* (On restriction) and *De distributionibus* (On distribution) are in fact elaborations of the theory of supposition. Ampliation is an extension of the supposition of a term. It occurs when an expression is combined with a modal term -- e.g. *homo potest esse Antichristus* (‘A man can be the Antichrist’), and *homo necessario est animal* (‘A man is necessarily an animal’) -- in which case the supposition of the the term ‘man’ is extended to more than just individuals existing in the present. The tract on *appellationes* is very short: appellation is considered no more than a special case of restriction, i.e. the restricted supposition brought about by a present-tense verb. In this tract the rules of appellation are in fact specific kinds of rules of restriction. The subject of restriction in general is discussed in the eleventh tract. The rules of restriction are the same ones as were presented in the early Parisian textbooks on logic.[9] The final tract, on distribution, deals with the multiplication of common terms as a result of their being combined with universal signs. These universal signs are either distributive of substance (such as *omnis*, *nullus*), or of accidents (such as *qualiscumque*, *quantuscumque*). In this description ‘substance’ is defined as substistent modes of being, and ‘accident’ as accidental modes of being. Separate attention is given to the universal sign *omnis* (‘all’ or ‘every’) along with a discussion of the common rule that the use of *omnis* requires three *appellata* (particular things). The most frequently cited example in these discussions in the thirteenth century was the sophisma *omnis phenix est* (‘Every phoenix is’). According to Peter of Spain, the use of *omnis* does not call for at least three *appellata*; an exception to this rule is found in cases in which there is only one *appellatum*, as

is the phoenix-case. The tract also pays attention to a number of tongue-twisting sophisma-sentences.

The *Syncategoreumata*

Peter's treatise on syncategorematic words forms part of a separate genre that developed from the beginning of the thirteenth century. The term *syncategorema* comes from a famous passage of Priscian in his *Institutiones grammatice* II , 15, in which a distinction is made between two types of wordclasses (*partes orationis*) distinguished by logicians, viz. nouns and verbs on the one hand, and *syncategoremata*, or *consignificantia*, on the other. The latter are defined as words that do not have a definitive meaning on their own, but acquire one only in combination with other, categorematic words.

Like the treatises of the *Tractatus* kind, the *Syncategoreumata* were developed from the (twelfth-century) theories on fallacies, as well as from grammatical doctrines (from the same period). From the second half of the twelfth century, there was a growing interest in the linguistic elements that are considered to lie at the basis of ambiguity and fallacious reasoning. Hence the increase of treatises presenting a systematic account of these terms. The connection these treatises have with Priscian's grammar can be gathered from the attention different authors pay to the *signa quantitatis* (or quantifiers), and the fact that considerable attention is given to the meaning and function of syncategorematic terms.

The list of words to be included among the *syncategoreumata* was not always the same. Generally speaking it comprised exclusive words *tantum* (only), *solus* (alone), exceptive words such as *preter* (except), *nisi* (unless), consecutive words such as *si* (if) and *nisi* (if not), the words *incipit* (begins) and *desinit* (ceases), the modal terms *necessario* (necessarily) and *contingenter* (contingently), the conjunctives *an* (or), *et* (and), *nisi* (unless), *in eo quod* (in that), and *quin* (that not). In Peter's work we also find a discussion of the terms *quanto* ('how much' or 'as much as') *quam* ('than' or 'as') and *quicquid* (whatever). Unlike some other authors (such as William of Sherwood and Robert Bacon), his list does not include the word *omnis*.

In the opening of his *Syncategoreumata*, Peter presents his rationale for this investigation, viz. that there is a close link between the use of these kinds of words in sentences and their truth-value. His idea is that the syncategoreumata must have some sort of signification, but not the same as the categorematic words. For this special kind of signification he uses the words *consignificatio* and *dispositio*.

The first two separate chapters of the *Syncategoreumata* are devoted to the words *est* and *non*, which are said to be implied in all other syncategorematic words. Peter's account of the first word focuses on the notion of *compositio* (composition), which is explained in great detail, by looking into the signification of nouns and verbs (signifying a composition of a quality with a substance, and that of an act with a substance respectively). Considerable attention is given to the composition featuring in the verb 'is', in the form of the question of whether the composition involved can be counted among beings or not, considering the fact that it can be used to express different kinds of states of affairs. The chapter on negation introduces the important distinction between an act as conceived of or in the manner of a concept (*ut concepta sive per modum conceptus*) and as carried out (*ut exercita*).[10] Among the former

type we find the noun ‘negation’ and the verb ‘to deny’, whereas the latter is what is meant by the negative particle ‘not’. The remainder of the chapter deals with the function of the negation, which is to remove the composition found in whatever it covers, and discusses some well-known sophisma-sentences which turn on the specific function of negation.

The third chapter of the *Syncategoreumata* discusses the exclusive words *solus* and *tantum*. They are called exclusives because they carry out an exclusion, not because they signify one. An exclusion, furthermore, requires four things, namely, what is excluded, what is excluded from, the respect in which it is excluded, and the act of exclusion. The kinds of exclusion are divided into general and specific: the former involves an exclusion from something generic, whereas the latter from something specific. Questions that come up in this section have to do with the results of adding an exclusive term to different kinds of words, such as to a term falling under the category of Substance: does it exclude only other substances, or does it also exclude from things listed under another category? And what if it is added to a term listed under the category of Accident (such as colour, quantity, and so on)? The next question deals with the sorts of terms that can be meaningfully associated with an exclusion. For example, is it possible to exclude something from ‘being’ (as in ‘Only being is, therefore nothing other than being is’)? The tract proceeds with the kinds of things that can qualify for an exclusion. The fourth chapter, which deals with exceptive words, is compiled in a similar manner.

The fifth chapter is about the word *si*, which is said to signify causality in or via antecedence. The chapter also contains discussions of the kinds of consecution or consequence, problems of inference connected with the referents of terms used in consecutive sentences, and also on how to contradict a conditional sentence. Special attention is given to the problem whether from the impossible anything follows.

The chapter on ‘begins’ and ‘ceases’ is a good example of the way in which extra-logical considerations found their way into medieval treatises on logic. Thus, apart from the semantics and inferential problems connected with the use of these words in propositions, the chapter also looks into the notions of motion and time. An important part of Peter's ontological views can be gathered from chapter seven, which covers issues connected with the use of modal terms. Chapter eight discusses the signification and use of connectives, and the final chapter on syncategorematic words proper is concerned with the expressions *quanto*, *quam* and *quicquid*. A very short concluding chapter of Peter's *Syncategoreumata* deals with a somewhat isolated topic, i.e. the proper modes of response in an argument. The topics looked into are solution, the quantity and quality of syllogisms, and the ways to go about proving a syllogism.

Doctrinal Elements in Peter's Logic

One of the most important elements in Peter's logic concerns the doctrine of supposition. The theory of supposition has its origins in the twelfth century, when the medievals showed a growing interest in the ways in which words function in different contexts. This way of dealing with the semantics of terms has been dubbed the "contextual approach".[11]

The primary semantic property of a word is its *significatio*, in Peter's definition, the "representation of a

thing by a word in accordance with convention". It is a natural property of a word, the presentation of some (universal) content to the mind. The *significatio* of a word depends on its imposition, i.e. the application originally given to the word in question. A word can have more than one *significatio*, if it was originally applied to two or more distinct (universal) natures.

The counterpart of *significatio,* the formal constituent of every meaning, is the word's capacity to "stand for" different things (even though its *significatio* remains the same), depending on the context in which it is used. In the early stages of the development of the theory on the properties of terms, this feature of a word was called *appellatio*. For instance, the words ‘man’ and ‘horse’ can be used to stand for different individual men or horses. But they can also stand for themselves, e.g. when they are used in sentences such as ‘man is a noun’, or ‘horse is a noun’. Moreover, their meaning can differ according as the words are used in combination with verbs of different tenses.

In the final stages of the development of the theory, the notion of supposition becomes the general label that covers all the uses of a noun (substantive or adjectival), to which other recognised properties of terms (*appellatio*, *ampliatio* and *restrictio*) are subordinated.

The theory of properties of terms shows a radical inconsistency, which has been explained as "the persistent hesitation of medieval logicians between the domains of connotation (universals) and denotation (individuals)."[12] This inconsistency runs throughout Peter's account of supposition, and comes to the fore most prominently in what he says about natural supposition (*suppositio naturalis*). The main problem is in what way the property of natural supposition is related to the term's *significatio*, which was defined as the acceptance of a word for a thing (*res*). By this definition, Peter's concept of *significatio* covers both the intension and extension of a term, the universal nature of man and the individuals that have this nature in common. *Suppositio naturalis,* on the other hand, is described as "the acceptance of a common term for all those things that can share in a common universal nature"; for example, the term ‘man’ when taken by itself by its very nature stands for all the individuals that fall under it, whether they exist in the past, present or future. From this definition and the example just presented it appears that the extensional features of *significatio* and *suppositio naturalis* overlap. The latter has been explained by interpreters as the natural capacity of a significative word to stand for something.

There is a more telling difference between *significatio* and *suppositio naturalis,* however. *Significatio* is the natural property of any significative term to represent things, owing to its original imposition, whereas a term's supposition only enters the scene when it is used. The expression "taken by itself" (*per se sumptus*) found in Peter's account of *suppositio naturalis,* does not mean that no context is required, as is the case in *significatio,* but it merely indicates that for the moment the actual context is being disregarded. The link between *significatio* and *suppositio* is the following. When some word has acquired a signification by an *impositor* (= someone who bestows a meaning upon a word), then it connotes a univeral nature or essence, and acquires a natural capacity to stand for all the actual and possible individuals that share in this common nature; it owes this capacity to its *significatio*. If, however, we disregard for a moment the actual context in which the term in question is used and look upon the term as taken by itself (*per se sumptus*), then its supposition covers its entire extension. If we take the factual context in which the term is used into consideration, then its extension becomes limited, owing to the

context. The context, or more precisely, the added significative term, can be of three kinds: the added significative term can be a predicate of a proposition in which the term at issue occurs, the added significative term can be an adjective, or the context can be of a social nature.[13]

The distinction between *significatio* and *suppositio naturalis* persisted throughout the thirteenth and fourteenth centuries. Behind it is the fundamental view that regardless of whether a word is used in some context or not, it always has a *significatum*, i.e. the universal nature or essence it signifies, which can be separated from what the word comes to mean in a specific context.

Besides *suppositio naturalis*, Peter's (and other medievals') conception of *suppositio simplex* also seems to hover between connotation and denotation. In the expression *homo est species* the term *homo* has *suppositio simplex*, but this is precisely too what the term *homo* signifies. So there scarcely seems reason to separate signification from supposition on this score. The specific use of *suppositio simplex* found in Peter of Spain and other medieval authors, as the representation of a universal nature, is rejected later on by authors such as William of Ockham. For the latter, the term *homo* in the example just given has *suppositio simplex* (for Ockham a special case of *suppositio materialis*) in that it stands for the mental concept of man.[14]

Peter of Spain's logical works reveal a realistic outlook. This can be shown from the way in which he discusses the use of the word *est* (is), his account of *suppositio simplex*, and the way he analyses the occurrence of the word ‘necessarily’ in propositions. Moreover, his conception of the consecutive expression ‘if’ clearly shows his tendency to put the domains of reality and language on a par.

In his *Syncategoreumata*, Peter analyses the significative function of the word ‘is’. To a certain extent his findings are not confined to that term alone, but cover all verbs, in which the verb ‘is’ is always understood. The most remarkable feature about his discussion of ‘is’ is his focus on the notion of composition. What he is particularly interested in is the kinds of things affirmative propositions featuring that verb can refer to, in his words, the type of composition involved in such propositions.

The notion of ‘composition’ plays a prominent role in Peter's semantics. before embarking on the specifics of the word ‘is’, he first looks into the *compositiones* involved in the noun and the verb. When it comes to the composition involved in the use of ‘is’, the starting-point for his account is the question whether the expression ‘is’ in a proposition of the form ‘S is P’ implies the ‘being’ of the composition. Whether it does or not depends on how we consider the composition. If we are talking about any composition whatsoever, in his words, the composition in general, the composition can indiscriminately be connected with beings and non-beings. This is because we can talk about both things that are and things that are not by making use of the same affirmative propositions. Hence anything expressed by a proposition of the form ‘S is P’ expresses a being in a certain sense (*ens quodammodo*). The type of composition he is referring to here is the mental content of some affirmation, which is something that only has being to a certain degree. However, the composition in general, that is, the state of affairs involved in such expressions, is primarily connected with being rather than non-being. It is when we talk about non-beings, such as chimaeras, that being in a certain sense once again enters the scene. Hence a distinction of the types of being referred to, or the types of composition involved in affirmative

propositions into being in the absolute sense (*ens simpliciter*) and being in a certain sense (*ens quodammodo*). The difference between these two types of being is illustrated by the distinction between two types of inference: from ‘A man is an animal’, in which the composition involved is a being in the absolute sense, it follows ‘Therefore a man is’, but from ‘A chimaera is a non-being’, in which the composition is a being in a certain sense only, it does not follow ‘Therefore a chimaera is’.

The counterpart of Peter's discussion of composition is the section on negation. Peter specifically goes into the question of what it is the negation denies. In his words, the negation removes the composition. The composition in this connection is identified with the affirmed state of affairs (*res affirmata*). What the negation removes is not the state of affairs, but the affirmation that goes along with it. The basis of both composition and negation turns out to be the same state of affairs, i.e. something that is formulated in the mind, to which we can either assent or deny to be the case.

The focus on matters of ontology is evidenced in other portions of Peter's logic as well. For Peter, as for Henry of Ghent (who also wrote a *Syncategoreumata*) the expression *homo* (man) in *homo est animal* (‘Man is an animal’) has simple supposition: it stands for the universal nature of humanity. Accordingly, the expression is necessarily true, even if no man should exist. The term ‘necessarily’ thus has ampliative force: it enables the subject term ‘man’ to refer to individuals not only existing in the present (which is the normal case when a present-tense verb is used), but also to those of the past and the future. This analysis runs contrary to what is found in some other *Syncategoreumata* authors, like Johannes Pagus and Nicholas of Paris, who maintain that the term ‘necessarily’ does not have ampliative force. Hence the expression *homo necessario est animal* (‘A man is necessarily an animal’) is only true on the condition that a man exists.

A similar point is made in connection with the use of modal terms. For Peter of Spain, logical necessity is based upon ontological necessity, or, the necessity of propositions has its foundation in the necessity of the things spoken about. Necessity is associated with different types of things, such as the relationships between certain concepts (such as genera and species), and the specific things the notions of which we come across in the different kinds of (scientific) knowledge (such as mathematical entities and their properties). His outlook on necessity is clearly revealed in his analysis of the inference *homo necessario est animal*; *ergo Sortes necessario est animal* (‘A man is necessarily an animal; therefore Socrates is necessarily an animal’). In his view the inference is not valid, because a transition is made from necessary being to a being at a certain time. For Peter then, the notion of necessity ultimately refers to a necessary state of affairs in reality, something that is always the case.[15]

A similar fusion of the domains of language and reality is found in Peter's account of the consecutive ‘if’, which he explains as signifying causality. Like his contemporaries he looks into the question of whether from the impossible anything follows. In his account, the notion of ‘impossibility’ can be taken in two ways, viz. impossibility as such, or absolute impossibility, which amounts to nothing, or the impossible state of affairs that is referred to when notions of things that do have a reality separately but are incompatible are combined in statements. From the latter type of impossibility, such as ‘A man is an ass’, something, but not anything can follow, e.g. ‘Therefore a man is an animal’. From impossibilities as such, e.g. ‘You know that you are a stone’, nothing can follow. The fundamental idea is that in order to be able

to have something follow, the antecedent in the consecutive relationship must be a something (*res*) of some sort.[16]

Moral Particularism

Moral Particularism, at its most trenchant, is the claim that there are no defensible moral principles, that moral thought does not consist in the application of moral principles to cases, and that the morally perfect person should not be conceived as the person of principle. There are more cautious versions, however. The strongest defensible version, perhaps, holds that though there may be some moral principles, still the rationality of moral thought and judgement in no way depends on a suitable provision of such things; and the perfectly moral judge would need far more than a grasp on an appropriate range of principles and the ability to apply them. Moral principles are at best crutches that a morally sensitive person would not require, and indeed the use of such crutches might even lead us into moral error.

The particularist's opponent is the generalist. Ethical generalism is the view that the rationality of moral thought and judgement depends on a suitable provision of moral principles.

1. Two Conceptions of Moral Principles

If we are going to debate the question whether there is a need for moral principles, we need some idea of what we mean by a ‘moral principle’. Unfortunately there are two radically different conceptions of what moral principles are. The first conception, the ‘absolute’ conception, takes a moral principle to be a universal claim to the effect that all actions of a certain type are overall wrong (or right). The principle

‘don't break your promises’ can be expressed in various ways: ‘it is wrong to break one's promises’; ‘all actions that involve breaking a promise are wrong’ -- and so on. On the absolute conception, these all mean that each and every action of breaking a promise is a wrong action, whatever else there may be to be said for it. Each such action is wrong overall, despite any redeeming features it may have.

There is a very different way of understanding a moral principle, as ‘contributory’ rather than as absolute. Understood in this second way, our principle maintains that if an action involves breaking a promise, that counts against it. The action is the worse for being a promise-breaking. Of course it may be the worse for being a promise-breaking but the better for some other feature that it has - that of being kindly intentioned, say. The contributory conception of moral principles allows that more than one principle can apply to the case before us, since it holds that each principle is, as it were, partial; each specifies how things are only in a certain respect. But actions have many relevant features, some counting in favour and others against. Whether the action is overall right or wrong can only be determined by the overall balance of right and wrong in it. The contributory principles do not themselves tell us how to determine that balance. They only specify contributions one by one, and leave us to work out how these add up. Some people suppose that the principles can themselves be ranked in order of importance; if that were right, it would be of some help to us in working out what matters most in a given case. Others suppose that there is no available lexical ordering of such a sort, and that the matter is left to unaided ‘judgement’.

Since there are these two quite different conceptions of what a moral principle says, our discussion will need to address both possibilities. If particularism is true, there is not much room for moral principles of either sort.

2. What the Particularist Does Not Believe

It is standard, at least in cultures informed by the Christian tradition, to think of the moral person as the person of principle. This person is the person who has learnt, or developed for herself, a sufficient range of sound moral principles (of either type), and who has sufficient skill at applying these principles to cases as they crop up. There is no need to underestimate the sort of skill that would be required for this; the matter is certainly far from mechanical. One needs judgement both to discern whether a principle applies at all and, if it does, what exactly it requires of one. Nonetheless, however difficult it may be, moral judgement is conceived here as the application of principles to cases.

If moral judgement is a rational enterprise, it must be subject to constraints of consistency. What is demanded of us when we are required to be consistent in our moral judgements? The answer is that we are required to apply our principles consistently, that is, to apply the same principle to similar cases. It is inconsistent to apply the principle ‘don't lie’ to cases involving one's friends and not to those that involve strangers. If you want to behave in that sort of way, your principle is going to have to be ‘don't lie to your friends’. What this tells us, of course, is that consistency is not the only requirement. Our moral principles are supposed to be impartial, and it is not obvious that the principle ‘don't lie to your friends’ meets this condition. But at least someone who takes it as his principle can tell the truth to his friends and

lie to strangers without inconsistency.

Why do we think of the moral person as the person of principle, and why do we think of moral judgement as subject to this sort of consistency contraint? (As we will see later, there are other forms that the consistency constraint could have taken.) The answer, I think, is that we suppose that without moral principles there could be no such thing as the difference between right and wrong. Rightness and wrongness are peculiar properties, and the only way that an action can get them is by being related to a principle in one way or another. So unless there are principles saying which sorts of actions are right and which wrong, none would be right and none wrong. If this were so, it would hardly be surprising that the good moral judge would be the person capable of following in her mind the way in which actions get to be right or wrong, which requires knowing the relevant principles and seeing that they have this effect here and that effect there. And it would be hardly surprising that consistency in judgement would amount to no more than applying similar principles to similar cases.

A rather different argument appeals not so much to a metaphysical need for principles as to an epistemological need. If there is a distinction between right and wrong actions, how are we to detect it? There must be a detectable difference between the properties of the right ones and the properties of the wrong ones. Now if an action is wrong, it is wrong because of certain other features it has -- the non-moral features that make it wrong. Those non-moral features will be detectable in the ordinary way, whatever that is. Good moral judges, having detected them, can somehow work out whether they make the action right or wrong. But if this ability is not a matter of magic, it must rest on an at least implicit knowledge of regularities connecting the non-moral features of actions and their moral properties. Moral principles specify such regularities. So if moral judgement is to be even possible, there must be a set of principles connecting moral properties to non-moral properties, contrary to what the particularist claims.

If this is our picture of the individual trying to decide what she ought to do, how are we likely to conceive of the way to resolve disagreements between two individuals? Of course there are the facts of the matter to be sorted out between them. Then presumably they have to try to agree at least on those principles which are to be taken as relevant (that is, to agree on the principles, and to agree that they are the relevant ones in the present case). Finally, they have to agree on the course of action that those principles recommend in the situation that faces them. This would be, as we might put it, a full resolution of any initial disagreement. Otherwise we are looking for a compromise of one form or another. It is possible, for instance, for a disagreement on the principles not to make any practical difference as things turn out, so that it can be left to be sorted out another day.

Overall, then, we are offered a way in which moral reasons work, and an account of the perfectly moral agent whose decision processes fit the way the reasons work, that is, fit the way in which an action can get to be right or wrong. But the way moral reasons work is probably very different from the way that other reasons work. Other reasons are not principle-driven. Morality is special, since without principles it is impossible. (Remember that the two arguments given above for the need for principles appealed to the special nature of rightness and wrongness, or of moral properties in general.)

3. What the Particularist Believes

The particularist believes, like the generalist, that the perfectly moral person is the person who is fully sensitive to the moral reasons present in the case. But the particularist paints a very different picture of what it is to be fully sensitive to those reasons. The particularist picture is one which takes moral reasons to operate in ways that are not noticeably different from the way in which other reasons function -- more ordinary reasons for action, say, or reasons for belief rather than for action. Morality may be distinguished by its subject matter, but moral thought does not have a distinctive structure.

If we are to form a view about what a full sensitivity to the reasons amounts, to, we need to have some picture of how moral reasons work. The core of particularism is its insistence on variability. Essentially the generalist demands sameness in the way in which one and the same consideration functions case by case, while the particularist sees no need for any such thing. A feature can make one moral difference in one case, and a different difference in another. Features have, as we might put it, variable relevance. Whether a feature is relevant or not in a new case, and if so what exact role it is playing there (the ‘form’ that its relevance takes there) will be sensitive to other features of the case. This claim emerges as the consequence of the core particularist doctrine, which we can call the holism of reasons. This is the doctrine that what is a reason in one case may be no reason at all in another, or even a reason on the other side. In ethics, a feature that makes one action better can make another one worse, and make no difference at all to a third.

Particularists suppose that this doctrine is true for reasons in general, so that its application to moral reasons is just part and parcel of a larger story. For an example that comes from a non-moral context, suppose that it currently seems to me that something before me is red. Normally, one might say, that is a reason (some reason, that is, not necessarily sufficient reason) for me to believe that there is something red before me. But in a case where I also believe that I have recently taken a drug that makes blue things look red and red things look blue, the appearance of a red-looking thing before me is reason for me to believe that there is a blue, not a red, thing before me. It is not as if it is some reason for me to believe that there is something red before, me, but that as such a reason it is overwhelmed by contrary reasons. It is no longer any reason at all to believe that there is something red before me; indeed it is a reason for believing the opposite.

Examples like this establish the variability of reasons for belief. Turning to reasons for action, we might point out that in some contexts the fact that something is against the law is a reason not to do it, but in others it is a reason to do it (so as to protest, let us say, against the existence of a law governing an aspect of private life with which the law should interfere). Examples of this sort can be multipled at will. They appear to establish the holism, or variability of reasons for belief and of ordinary reasons for action. The particularist suggests that there is no reason to suppose that moral reasons function in a radically different way from other reasons. Indeed, there is a sort of presumption that they don't. That presumption is partly grounded on the fact that nobody is able to say with any confidence just which reasons are moral ones and which are not. This means that providing a radical difference between the way in which reasons of the two sorts function should seem rather peculiar. But the presumption is also partly grounded in the fact

that the difference suggested by the generalist is very radical, since it affects what one might call the very logic of moral thought. To suppose that moral thought has a different logic from other thought is to adopt a bifurcated conception of rationality. Moral rationality is principle-bound, based on invariant reasons. Other forms of rationality are nothing like this at all. Particularists think that this suggestion is very strange.

These points about holism or the variability of reasons need to be expressed in different ways, according to the conception of principles that they are aimed at -- the absolute or the contributory. Principles of both sorts aim to specify invariant reasons, but the reasons they specify are rather different in style. Absolute principles, which specify a feature or combination of features that always succeed in making an action wrong (or right) wherever they occur, purport to specify an invariant overall reason, as we might put it. Counter-examples to suggested principles of this sort will consist in cases where the supposed feature or combination of features is present but the action concerned is not wrong overall (or right overall). Contributory principles are different. They purport to specify features that always make the same contribution, irrespective of context. Counter-examples to suggested contributory principles consist of cases where the feature cited is present but either does not count at all or counts the wrong way (a supposed right-making feature actually making an action worse rather than better, for instance). Particularists take their holism to be a reason to reject any invariance of reasons, of either sort -- whether at the overall or at the contributory level. Reasons as such, they say, do not need to behave in this sort of way. It is consistent with this, however, to allow that there might be some invariant reasons. What the particularist says, however, is that the possibility of morality in no way depends upon a suitable provision of invariant reasons of the sorts that principles are attempting to specify. Principle-based accounts of morality, such as those that specify ten (or some other number) of basic moral principles (e. g. Gert 1998), are left looking rather peculiar.

The picture so far is that actions get to be right or wrong in a wide variety of ways. Particularists are 'pluralists', believing that there is more than one morally relevant property. Many properties (or features) are capable of making a difference to how one ought to act, and are therefore capable of being morally relevant. But a property can be relevant on one occasion and not on another, and can count in favour of action here and against action there. Isn't this all terribly confusing? If it is all as much of a mess as this, how are we capable of keeping track of it? Are we reduced to looking at the case before us and hoping that the complex interrelations between the various features that happen to be relevant here will just strike us, somehow? Is there no such thing as general moral knowledge that one can extract from experience and bring to bear on a new case? Particularists need not deny this possibility. The question will be what form such general moral knowledge will take if it is not knowledge of the sort of invariabilities that particularism sets its face against, and that principles try to capture. I suggest that what the experienced moral judge knows is a range of ways in which a feature can contribute to determining how to act. There need be no hard core to this set of 'sorts of contribution', no common element, no limited set of paradigm cases. Instead, in understanding the practical purport of a concept such as cruelty, what one knows is the sort of difference it can make that what one proposes to do would be cruel, in a way that enables one to see new differences made in situations rather different from those one has encountered so far. Particularists may suggest that this is rather like what one knows when one knows the semantic purport of a term. In knowing the semantic purport (= the meaning) of 'and', one is in

command of a range of contributions that ‘and’ can make to sentences in which it occurs. There need be no ‘core meaning’ to ‘and’; it would be wrong to suggest that ‘and’ basically signifies conjunction. If you only know about conjunction, you are not a competent user of ‘and’ in English, for there are lots of uses that have little or nothing to do with conjunction. For example: two and two make four; ‘And what do you think you are doing? (said on discovering a child playing downstairs in the middle of the night); John and Mary lifted the boulder; the smoke rose higher and higher. Those competent with ‘and’ are not unsettled by instances such as these, but nor are they trying to understand them in terms of similarity to a supposed conjunctive paradigm or core case. Particularists in ethics will want to say the same sort of thing about what one knows when one knows the practical purport of a concept; one becomes familiar with its practical grammar. There is complexity, then, but it is manageable complexity.

This tells us how particularists will conceive of moral deliberation, when an individual tries to work out for herself how to act. There is no attempt to bring principles to bear on the situation, but there is an attempt to work out what matters here and how it matters, in ways that may involve an indirect appeal to the way things were or might be elsewhere. And when two particularists are engaged in dispute, it is not as if they are reduced to saying ‘I see it this way’. There are ways of supporting or defending the way one takes the situation to be. A particularist can perfectly well point to how things are in another perhaps simpler case, and suggest that this reveals somthing about how they are in the present more difficult one. There need be no generalist suggestion that since this feature made a certain difference there, it must make the same difference here. But our judgement can be informed, and indeed defended, by seeing the way in which a feature functions in situations that resemble the present one in various ways. What we learn is not how things must be here, but how they might very well be. Argument between two people who differ on the way to see the present case can make progress as each brings to bear other situations that are both appropriately different from and also appropriately similar to the one before them. There is no guarantee that this process will lead to agreement, any more than the generalist understanding of how disagreements get resolved leads us to suppose that all disagreements are resoluble, if treated properly. But things can happen even where there is no guarantee that they will happen.

Finally, in this section, how does the particularist understand someone who says ‘that is stealing, and therefore you should not do it’? One way of understanding what is said here is as an abbreviated argument, which fully specified reads ‘that is stealing and stealing is always wrong; therefore that is wrong’. This reading introduces silent appeal to a principle -- either absolute or contributory, according to one's way of understanding ‘that is wrong’. And it suggests that what we have here is really an inference, or argument, with premises and a conclusion. This is not how the particularist is likely to see things. Particularism is likely to think of ‘that is stealing and therefore it is wrong’ as saying ‘that is stealing and wrong for that reason’. This is not an argument, and there is nothing going on here that really merits being called inference. It is simply an account of the presence of a reason and a statement of what reason it is; that is, of what it is a reason for (or against).

4. Problems for Absolute Principles

The previous section tried to lay out the main aspects of the particularist conception of moral thought,

and of the way in which actions get to be right and wrong. Particularists do not, however, restrict themselves to expounding their own view. Of course, they are likely to say that their view is at least possible, and that generalism tends merely to assume otherwise and then to carry on blithely. The mere possibility that particularism be true is of some importance in the dialectic. But there are also reasons for doubting whether any form of generalism can really be true. Some of these have already emerged; these involved the attempt to establish a broad holism of reasons, by appeal to examples. There are replies to such attempts, which we will consider below (in Problems for Particularism); the replies amount to the claim that, despite appearances, holism must be false.

In the present section we consider reasons for thinking that morality cannot be a system of absolute principles.

The first reason is that absolute principles cannot conflict, and that if they cannot conflict a vital aspect of our moral lives (that is, conflict) has been left out of account altogether by any theory that supposes that morality is entirely governed by absolute principles.

If two supposed absolute principles conflict in a single case, one of them must be abandoned. Suppose, for instance that one principle says that all actions of type A are wrong and another says that all actions of type B are right. Suppose also that no action can be both overall wrong and overall right, and that it is possible for an action to be of both types, A and B. Things are all right so far, but if there were an action of both types, one or other of the principles would have to have abandoned. But this means that we have no room for conflict. What is meant by moral conflict here is not conflict between two individuals, but conflict between reasons for and against in a given case. There cannot be that sort of conflict, if all reasons are specified in absolute principles, because if the reasons conflicted the principles specifying them would conflict, and this would just show that one of the principles was a fraud. Conflict would, then, never be more than a product of our own misconceptions. There would be no real conflict.

What this criticism amounts to is the complaint that we need to be able to make sense of cases in which there are moral reasons on both sides, for and against. But we cannot do this effectively if all moral reasons are specified in absolute principles. Morality cannot, therefore, be just a system of absolute principles. The only way in which we could continue to think of morality as governed by absolute principles is to suppose that there is only one such principle, so that there is no possibility of conflict between principles, or to arrange things in some other way so that the principles are incapable of conflict. (Even then, of course, there would be the worry that conflict is real, and that to arrange things so that conflict is merely apparent is to erase something important.) We know of one position that offers only one principle: classical utilitarianism. The argument against this ‘monistic’ position is rather different. The argument is the direct claim that monism is false; there is more than one sort of relevant property, or more than one way in which features can get to be morally relevant. So a position with only one absolute principle is false, and one with more than one such principle cannot make proper sense of conflict.

5. Problems for Contributory Principles

The best form of generalism, therefore, probably tries to do the whole thing in terms of contributory principles -- principles that specify considerations that always count as contributory reasons. In this picture it is quite possible for there to be reasons on both sides. The classic example of such a theory is W. D. Ross's theory of Prima Facie Duties (see his 1930, ch. 2). This is just an attempt to put into good theoretical order our untutored intuitions that there are many different sorts of things that can make a difference to how we should act. There is a principle that says ‘Be just’, but this does not mean that all just actions are in fact right; it only means that the justness of an action counts in its favour, or that an action is the better for being just. Sadly, an action can be just but still wrong for other reasons. This means that it can sometimes be morally required of us that we act unjustly. If it is, there will be features of the situation that require it of us; perhaps we owe an enormous debt of gratitude, or perhaps by this unjust action we can save Holland from flooding.

The generalist who takes this line supposes, qua generalist, that a feature that makes a difference in one case will make the same sort of difference in every case, and that there will be a contributory principle specifying its regular contribution. This is what particularism is concerned to rebut. Particularists applaud Ross's insistence that there can be many features of the situation each of which makes some difference to how one should act; they merely want to say that the matter is not regular in the way that Ross, as a generalist, supposes. They have three points to make, then. The first involves producing counter-examples to suggested regular contributors. Ross supposes, for instance, in accordance with long tradition, that the fact that one has promised to do something is always some reason to do it. A counter-example to this claim would be a case where, for peculiar reasons no doubt, the fact that one has promised to do something is either no reason to do it or even a reason not to do it. Suppose, for instance, that I have promised not to keep my next three promises; what then? Again, does one always have at least some reason to tell the truth? A little bit of ingenuity enables one to come up with a case in which the fact that this is true is a reason not to say it. And so on.

The second prong of the particularist attack is to ask why we should suppose that a feature that counts in favour in one case must count the same way wherever it appears. To this question, I think, no real answer has been produced. Generalists tend to point out that if one claims that a feature counts in favour here and against there, one has something to explain. But the particularist is happy to admit this. It is true that if a feature counts in favour in one case and against in another broadly similar case, there must be an explanation of how this can be. That explanation will presumably be given by pointing to other differences between the cases. In the second case, perhaps, something that is required for the feature to count in favour is in fact absent, though it was present in the first case. Such explanations must be available, and they can be found. None of this does anything to restore a generalist conception of how reasons function.

The third prong of attack on contributory generalism involves asking for an appropriate epistemology. How are we to tell, from what we can discern case by case, that this feature will function in the same way wherever else it appears? Ross, our generalist, holds that we start with the recognition that this feature counts in favour here, but that we can immediately tell (by a process which he calls ‘intuitive induction’) that it must count in favour everywhere. The question is how this is suppposed to work. What is it that is discernible in one case and tells us that what we have here must repeat in all other cases? (Ross rightly

does not suppose that we learn our moral principles by ordinary induction.) The standard, and probably the only, answer to this question is wrong. This answer amounts to an account of what it is to make a difference in a particular case -- what it is to be relevant here. That account, understands a feature as relevant here if and only if, *in any case where it is the only relevant feature, it would decide the issue*. Now if this account of particular relevance were defensible, we would indeed have some reason to suppose that what is relevant here would be relevant in any other situation. For on each further situation it will still be true that if it were the only relevant feature, it would decide the issue. So relevance is indeed general relevance, on this showing. And this gives the generalist the epistemology he needs, for it is now easy to see how, in discerning that this feature matters here, we immediately see that it would make the same difference on every occurrence. For it is true of it on each occurrence that if it were the only relevant feature, it would decide the issue.

Sadly, the account of relevance that this all depends on is not defensible. It is, after all, true of any feature whatever that if it were the only relevant feature, it would decide the issue. The word ’relevant’ appears within this formulation, and it cannot be removed. For if we said merely that if this feature were the only feature, it would decide the issue, we would have said something that is probably both false and, worse, incoherent. It would be incoherent because the idea that a feature could be present alone, without any other features whatever, is surely nonsense. The idea that an action could be merely kind, say, without having any other features at all, makes no sense at all. Further, there may be some features that can only be relevant if some other feature is also relevant -- features that (in terms of reasons) only give us reasons if some other feature is giving us reasons as well. For instance, in the Prisoner's Dilemma one prisoner only has reasons if the other one does. If this can occur, any ‘isolation test’ for reasons must miss some reasons. Finally, trying to isolate the contribution of a feature by asking how things would have been if no other feature had made any contribution is, when one comes to think of it, a rather peculiar entreprise. It is uncomfortably like trying to determine the contribution made by one football player to his team's success today by asking how things would have been if there had been no other players on the field. So the notion of relevance that is required as a basis for generalist epistemology is unacceptable.

6. The Generalists' Reply

Generalists have two possible replies to these attacks, assuming always that they accept that many of the contributory principles that they originally suggested have been refuted by counter-example. The first thing they can do is to complicate the principles. The second thing they can do is to restrict their generalism to a limited group of reasons.

Taking the first tack, one might suggest that if the fact that one has promised is in some cases not a reason for doing what one promised to do, there will be some explanation of this. Suppose that the explanation is that what one promised to do was immoral. All one needs to do is to suck this feature into one's account of the supposedly general reason. So now the reason in ordinary cases will be that one promised to do it and it is not immoral. We might object that not even this is always a reason. What if one's promise has been extracted by duress? The response will be to suck that into the reason as well. This reason is growing all the time; now it is that one promised to do it, that it is not itself immoral, and

one's promise was not made under duress. This battle can continue; it has no obvious stopping point. Still, we might say, eventually ingenuity will give out, and we will reach a (now very complex) specification of a reason to which we can think of no appropriate counter-example.

But note what has happened here. We started from a consideration which we took to count in favour of our action, and we have ended with a complex specification of something that plays rather a different role. What we got at the end was more like an elaborate guarantee that something mentioned in the guarantee counts in favour of the action. Consider the promising example above. That I promised does, let us suppose, count in favour of my acting. But that my promise was not made under duress does not do that at all. It functions as an enabling condition, one in whose absence the first feature (that I promised) would not have been the reason it is. It is not itself a reason to do the action; that role is distinctive, and it is played here only by the fact that I promised. Note, further, that the combination of that reason and this enabling condition is not itself a (further) reason in favour of doing the action. So the distinction between ‘counting in favour’ and ‘enabling something else to count in favour’ is significant, as particularists see things. What the generalist reached, in defending her supposed reason by complication, is therefore not itself a reason at all, but only a guarantee (when finally complete) that there is a reason somewhere within it. And why should we suppose that nothing can be a reason unless we can specify a condition that guarantees its status as a reason, and that it is only a reason when present in a larger state within which it is guaranteed to serve as such? No obvious answer occurs. The whole enterprise of defending one's reason by complication begins to look strangely irrelevant, and its product unnecessary. One would have thought that there can be reasons that can function perfectly well without this sort of guarantee. And the reasons given on behalf of generalism above (in What the particularist does not believe) do nothing to show otherwise.

The second generalist line of defence involves drawing in one's horns a little. Ross distinguishes between derived and underived prima facie duties. The underived ones are the duty to do the just thing, to act for the best, not to cause harm, to keep promises, and so on. Other duties are derived from these. So there is, as we might put it, a core of invariability surrounded by a variable periphery. I might have a duty to go up to London today to see my son Hugh. But this duty is derived from a general duty to do what I have promised to do. As we might put it, that Hugh is expecting to see me today sometimes gives me a reason to go up to London and sometimes does not; it is a derived, and therefore variable, reason. If it does give me a reason, it will because it is keyed in some way into an unvariable, underived reason. So derived reasons are variable, and underived ones invariant. On this account, counter-examples will only do damage if they are aimed at the supposed underived reasons. (See McNaughton and Rawling 2000.)

A different version of this picture maintains that invariant reasons derive from the virtues (see Crisp 2000). That an action is generous, honest, just, thoughtful, or helpful is always a reason to do it. The invariant core is given by the virtues, therefore, and the variant periphery depends upon that invariant core. This last point is important, because this defence of generalism needs to show why it is that morality requires a basis of invariance. Just to come up with a few invariant reasons is nothing to the point. Those who suppose they can seriously damage particularism by specifying a few (probably fairly complex) invariant reasons do little to show that moral thought depends (as it was put in the introduction above) on a suitable provision of principles (which we are now understanding as ’invariant reasons’).

The suggestion we are dealing with now does well in this respect. We are offered an invariant core and an account of why there must be such a core if moral thought is to be possible at all.

Of course, for the suggestion to work, it must be the case that the virtues function invariantly. Particularists are likely to say, for instance, that an action can be considerate without necessarily being the better for it. It may be considerate to wipe the torturer's brow, but this fact hardly functions as a reason to wipe, or makes his sweat a reason for us to wipe it off. The torturer's other activities prevent what would ordinarily give us a reason from doing so here. Similarly, it may be that a cruel response is exactly the one called for in the circumstances; cruelty, according to particularists, need not be an invariant reason. A generalist reply to these suggestions depends on showing that similar remarks cannot be made about (a sufficient range of) the other virtues.

What is at issue between particularism and generalism is the nature of moral rationality. Particularists maintain that there can be reasons -- moral reasons -- even if the features that give us those reasons function variably rather than invariably in their reason-giving. Generalists suppose that this is not possible. They claim either that all reasons, when properly understood, must function invariably, or that there is an invariant core even if there is a variable periphery. To argue for the first claim, they often demand, for each reason, that there be a discoverable guarantee of its status as such. But until they have offered some justification for this demand, their generalism will rest on nothing. Crisp's position is a model of the second approach because it offers an account of why the variability that the particularist is so fond of pointing to must be built around an invariant core. But I would say that the supposed virtues do not in fact play the role required here.

7. Do Particularism and Generalism Differ in Practice or Only in Theory?

Particularists are fond of saying that generalists will make bad decisions. One reason for this is that generalism seems to validate certain patterns of argument that particularists would think of as invalid. For instance, a generalist might think ‘Feature F made a difference in that case; so it must make the same sort of difference here too’. If our decision in the second case was influenced by such ’reasoning’, it would have been influenced by a mistake, according to the particularist. Particularism supposes that one cannot extract from one case anything that is guaranteed to make a difference to another. They recommend keeping one's eyes firmly fixed on the case before one rather than trying to squeeze an answer to one problem out of the answer to another. This does not show that there is nothing to be learnt from other cases. Particularists can even allow that it might, on occasion, be impossible to see the right answer here if one does not work to that answer from consideration of other cases, suitably constructed or provided by experience. One can perfectly well say ‘this feature mattered there, and so it might well matter here -- I had better have a look and see whether it does or not’. What one cannot and should not do is to say ‘it mattered there and so it *must* matter here’. So particularists allow a relevance to moral experience; they are not reduced to just gazing vacantly at the case before them and coming up with an answer that somehow seems appropriate. There is a practical difference between particularism and

generalism, but it is not this.

There is another possible practical difference between the two. This comes out when we consider two pretty similar cases of which we nonetheless want to make different judgements. Nobody supposes that this is impossible. The question is rather what is rationally required of the judge in such a case. The generalist might end up demanding that one make the same judgement in both cases unless one can provide a principle that distinguishes them. The particularist, by contrast, might demand only that one make the same judgement in both cases unless one can offer some reason for not doing so. Some, however, would not even demand that. All agree that there must be some relevant difference between any two cases of which one wants to make different judgements. Might it be enough to allow that there is some such difference, even though one has no idea what it is? Or is one rationally required to be able to make some suggestion about what it is? Or is one's suggestion to be formulated as a possible principle governing all similar cases? Particularists might be distinguished from generalists by their answer to these questions.

8. Problems for Particularism

People reject the persuasive charms of particularism for, broadly, two sorts of reasons: reasons to do with rationality, and reasons to do with motivation. I take rationality first. Three points are made. The first and most direct is that thinking rationally requires at least that one think consistently, and in ethics this just means taking the same feature to be the same reason wherever it occurs. Particularism, therefore, denies the rationality of moral thought. Second, what is the difference between moral choice and choosing chocolates? The difference is that when choosing morally we are required to make similar choices in similar circumstances; not so for the choice between rum truffles and peppermint creams. Third, what account can the particularist give of our ability to learn from our moral experience? Such moral self-education is certainly possible. An adolescent who has so far refused to accept that tact is a virtue can be brought to see the importance of being tactful in a particular case, and is then in a position to apply this knowledge more generally. The generalist can understand this as the extraction of a principle from an earlier case, which we then apply to later ones. What can the particularist offer as an alternative account?

Of these three points, the third is the hardest. The answer to the first is that, when we are thinking of reasons for belief, the sort of consistency required of us is merely that we do not adopt beliefs that cannot all be true together. Why should we understand the consistency requirement in a different way when we turn to moral reasons? Simply to insist that this is so must be to beg the question against particularism.

The second question asks us to justify a distinction between matters of whim, such as the choosing of chocolates, and matters of weighty reasons, such as those involved in moral choice. But this need not be a problem. Moral reasons as the particularist understands them occur in the one case and not in the other. Nothing at all like them applies to the choosing of chocolates (normally). This does nothing to show that in morality, unlike in the area of whim, we are required to make similar choices in similar situations. There are quite enough other differences between morality and whim.

The third question asks us what relevance other cases do have to a new case, if not the sort of relevance that the generalist supposes. The answer to this is that experience of similar cases can tell us what sort of thing to look out for, and the sort of relevance that a certain feature can have; in this way our judgement in a new case can be informed, though it is not forced or constrained, by our experience of similar cases in the past. There is no need to suppose that the way in which this works is by the extraction of principles from the earlier cases, which we then impose on the new case.

So much for one sort of complaint. I now turn to questions which focus on motivation. The general idea here is that a particularist morality is a lax morality: without principles, anything goes. But there are various ways in which this thought can be built up. The first is just to say that morality is in the business of imposing constraints on our choices. For there to be constraints, there needs to be regulation, and regulation means rules, and rules mean principles. This, however, is just wrong. There can be fully particular constraints on action, and the judgement that this action would be wrong is surely just such a thing. Constraints do not need to be general constraints, any more than reasons need to be general reasons.

Another line is that the person of principle will be unbudgeable; having taken a stand on an issue, he will not be moved from it. A particularist will not be like this. But here I have two things to say. First, nothing prevents a particularist from being of firm conviction case by case; an unbudgeable conviction need not be founded on principle, but simply on the nature of the case. Unbudgeability and principle have nothing essentially in common. Second, even if it were true that a principled person will on some points be unbudgeable, the question is whether those points are the right points. The worrying thought is that they might not be -- that in being driven by principle, our principled person will distort the relevance of relevant features by insisting on filtering them through principles, in a way that is at odds with the falsehood of generalism. In my view, unbudgeability and principles go very badly together. Unbudgeability may be a virtue in its place, but to be unbudgeably involved in a distortion is not a great triumph. If you are going to be incorrigible you had better always be right; incorrigible error is the worst of all worlds.

A different suggestion is that morality has the sort of authority over us that can only be provided by a rule. Here, however, I think that particularists should simply dig their heels in, and insist that moral reasons have all the authority they need already. She needs medical help, and I am the only person around to summon it. This situation demands a certain response from me, in a way that has authority over me because there is nothing that I can do to get out of it.

Still, we might say, there is the ever-present danger of backsliding in ethics; we see the right, but somehow cannot bring ourselves to do it. With principles, we have something capable of stiffening our waning resolve. Without principles, we will fall short all too often. One answer to this is that it is an empirical hypothesis for which there is little real evidence. What is more, the need for moral stiffening only arises once we have already decided what morality requires of us here, and the real question was whether that decision needed to be based on principle. As far as the point about backsliding goes, it does not; the need, if any, for principles comes later.

More to the point might be a worry about special pleading. This is different from backsliding, because the special pleader is the person who makes exceptions in their own favour. It would not be right for most people to do what I propose to do, but I am special; so I am left off the moral hook that others are caught by. This sort of special pleading occurs in the process of making our moral decision; it is not to do with motivation thereafter, as backsliding is. With backsliding I say ‘this is wrong but I am going to do it all the same’; with special pleading I say ‘this would be wrong for others, but not for me’.

The reason there is a genuine worry about special pleading is that one can always find some difference between this act and a plain duty, and there seems to be no way, within the resources available to particularism, to prevent such differences from being appealed to by those who, in bad faith, want to let themselves off the moral hook. A principle, we might say, would, or at least should, stop this sort of thing.

What is really going on here is that we are appealing to principles to rectify a natural distortion in moral judgement. If such judgement focuses only on the reasons present in the case before us, it is all too easy to twist those reasons to suit oneself. So we use principles to stop ourselves from doing that. But really the remedy for poor moral judgement is not a different style of moral judgement, principle-based judgement, but just better moral judgement. There is only one real way to stop oneself distorting things in one's own favour, and that is to look again, as hard as one can, at the reasons present in the case, and see if really one is so different from others that what would be required of them is not required of oneself. This method is not infallible, I know; but then nor was the appeal to principle.

Logical Form

Some inferences are impeccable. Consider:

> (1) John danced if Mary sang, and Mary sang; so John danced.
>
> (2) Every politician is deceitful, and every senator is a politician; so every senator is deceitful.
>
> (3) The tallest man is in the garden; so someone is in the garden.

Such reasoning cannot lead from true premises to false conclusions. The premises may be false. But a thinker takes no epistemic risk by endorsing the conditional claim: if the premises are true, then the conclusion is true. Given the premises, the conclusion follows immediately--without any further assumptions that might turn out to be false. By contrast, it would be very risky to infer that John danced, given only the assumption that Mary sang. More interesting examples include:

> (4) John danced if Mary sang, and John danced; so Mary sang.
>
> (5) Every hairless biped is a bird, Tweety is a hairless biped; so Tweety can fly.
>
> (6) Every human born before 1850 has died; so every human will die.

Inference (4) is not secure. Suppose John dances whenever Mary sings, and he sometimes dances when Mary doesn't sing. Similarly, (5) relies on unstated assumptions--e.g., that Tweety is not a penguin. Even (6) falls short of the demonstrative character exhibited by (1-3). While laws of nature may preclude immortality, it is conceivable that someone will escape the grim reaper; and the conclusion of (6) goes beyond its premise, even if it is (in some sense) foolish to resist the inference.

Appeals to logical form arose in the context of attempts to say more about this intuitive distinction between impeccable inferences, which invite metaphors of security and immediacy, and inferences that involve a risk of slipping from truth to falsity. The motivations for saying more are both practical and theoretical. Experience teaches us that an inference can initially seem more secure than it is; and if we knew which inferences are risk-free, we might be more alert to the points at which we risk error. (Such alertness might be valuable, even if the risks are tolerable.) Claims about inference are also connected, in various ways, with claims about thought and its relation to language. So we would like to know *in virtue of what*, if anything, an inference is impeccable. The most common suggestion has been that certain inferences are absolutely secure by virtue of their (logical) form; although conceptions of form have

evolved in tandem with conceptions of logic and language.

---

1. Patterns of Reason

An ancient thought is that impeccable inferences exhibit patterns that can be characterized schematically by abstracting away from the specific contents of particular premises and conclusions, thereby revealing a general form common to many other impeccable inferences. Such forms, along with the inferences that exemplify them, are said to be *valid*. With regard to (1), it seems that the conclusion is part of the first premise, and the second premise is another part of the first. We can express this point by saying that (1) is an inference of the form: **B** if **A**, and **A**; so **B**. And many other inferences, like (7), share this form:

(7) Chris swam if Pat was asleep, and Pat was asleep; so Chris swam.

The Stoics discussed such inferences, all of which are equally secure, using numbers (instead of letters) to reflect the abstract form: if the first then the second, and the first; so the second. In addition to this variant of '**B** if **A**, and **A**; so **B**', the Stoics formulated other valid schemata:

If **the first** then **the second**, but not **the second**; so not **the first**.

Either **the first** or **the second**, but not **the second**; so **the first**.

Not both **the first** and **the second**, but **the first**; so not **the second**.

Schematic formulations like these require variables. And let us introduce 'proposition' as a term of art for whatever the variables above (represented in bold) range over. Propositions are thus the sorts of things that can be true or false; for they are potential premises/conclusions--things that can figure in valid

inferences. (This leaves it open what propositions are: sentences, states of affairs, or whatever.)

We can now draw an important distinction. In speaking of an inference, one might be talking about (i) a mental *process* in which a thinker draws a conclusion from some premises, or (ii) the *propositions* a thinker would accept (perhaps tentatively or hypothetically) if she accepted the premises and conclusion, with one proposition designated as an alleged consequence of the others. The latter notion seems to be primary with respect to what makes an inference risk-free. For a risky thought process is one in which a thinker who accepts certain propositions comes to accept, without further evidence, a proposition that does not follow from the initial assumptions. So let us focus on premises and conclusions, as opposed to episodes of reasoning; and let us assume that propositions themselves have forms. Then the inference

> (1) John danced if Mary sang, and Mary sang; so John danced.

is secure, in part *because* its first premise has the form '**B** if **A**'. If the proposition lacked this form, one could not explain the impeccability of (1) by saying that '**B** if **A**, and **A**; so **B**' is a form of valid inference.

It is not obvious that *all* impeccable inferences are instances of some valid form, and thus inferences whose impeccability is due to the forms of the relevant propositions. But this thought has served as an ideal for the study of inference, at least since Aristotle's treatment of examples like

> (2) Every politician is deceitful, and every senator is a politician; so every senator is deceitful.

The first premise in (2) seems to have several parts, each of which is a part of the second premise or the conclusion; and the inference is presumably valid because these proposition-parts exhibit the right pattern. Aristotle (who predated the Stoics) captured this idea by noting that conditional claims of the following form are sure to be true: if every *P* is *D* and every *S* is a *P*, then every *S* is *D*. Correspondingly, the following inference schema is valid:

> Every *P* is *D*, and every *S* is a *P*; so every *S* is *D*.

Aristotle discussed a range of such inferences, called syllogisms, involving quantificational propositions---indicated by words like 'every' (or 'all') and 'some'. Two other syllogistic forms are expressed below as valid schemata, although Aristotle typically presented his syllogisms as conditional claims:

> Every *P* is *D*, and some *S* is a *P*; so some *S* is *D*

> Some *S* is not *D*, every *S* is a *P*; so some *P* is not *D*.

These (italicized) variables are intended to range over certain *parts* of propositions. There is a sense in

which common nouns like ‘politician’ and adjectives like ‘deceitful’ are *general*, since they can apply to many individuals; and just so, it seems, propositions contain correspondingly general elements. For example, the proposition that every senator is deceitful contains two such elements, both of which are relevant to the validity of inferences involving this proposition.

Propositions thus seem to have structure that bears on the (im)peccability of inferences, even ignoring premises/conclusions with propositional parts. That is, even ‘simple’ propositions have logical form. As Aristotle noted, pairs of such propositions can be related in interesting ways. If every *P* is *D* (and there is at least one *P*), then some *P* is *D*. If no *P* is *D*, then some *P* is not *D*. It is certain that either every *P* is *D* or some *P* is not *D*; and whichever of these propositions is true, the other is false. Similarly, the following propositions cannot both be true: every *P* is *D*; and no *P* is *D*. But it is not certain that either every *P* is *D* or no *P* is *D*. (Perhaps some *P* is *D* and some *P* is not *D*.) This network of logical relations strongly suggests that the propositions in question contain a quantificational element; two general elements; and sometimes, an element of negation. This raises the question of whether other propositions have a similar structure.

2. Propositions and Traditional Grammar

Consider the proposition that Venus is bright, which can figure in inferences like

> (8) Every planet is bright, and Venus is a planet; so Venus is bright.

Aristotle said little about such inferences. But others formulated the schema ‘every *P* is *D*, and *n* is a *P*; so *n* is *D*’, where the new variable is intended to range over proposition-parts of the sort indicated by names. (On some views, discussed below, the proposition that Venus is bright contains a quantifier and two elements of generality; though unsurprisingly, such views are tendentious.) In any case, Aristotle knew about propositions like the conclusion of (8). Indeed, he thought such propositions exemplify a subject-predicate structure shared by all propositions--and the sentences that indicate (or express) them.

The *sentence* ‘every politican is deceitful’ intuitively divides into two major parts, as shown by the slash: ‘every politician / is deceitful’. Similarly for ‘Venus / is bright’, ‘some politician / swam’, and ‘the brightest planet / rises early in the evening’. Until fairly recently, it was held that every declarative sentence can be divided into subject and predicate in this way, *and* that propositions were like sentences in this respect. Aristotle would have said that in ‘Venus is bright’, (the property of being) bright is predicated of Venus; in ‘every *P* is *D*’, *D* is predicated of every *P*. Thus, ‘Venus’ and ‘every politician’ can both indicate subjects; and the word ‘is’ introduces a predicate. Using slightly different terminology, other theorists treated all elements of generality as predicates, and propositions with the following structure were said to have *categorical form*: subject-copula-predicate; where a copula, indicated by words like ‘is’ or ‘was’, links a subject (which can consist of a quantifier and predicate) to a predicate.

In this context, it is relevant that sentences like ‘Every man swam’ can---with some awkwardness---be

paraphrased by sentences like ‘Every man was a swimmer’. So perhaps both sentences indicate the same proposition, while the second better reflects the true categorical form of the proposition. Maybe ‘swim’ is an abbreviation for ‘was a swimmer’, in the way that ‘bachelor’ is arguably short for ‘unmarried man’. (One would violate English grammar by saying ‘Every man was swimmer’; the article ‘a’ is needed. But let us assume that this feature of English, not found in all languages, is not reflected in propositions.)

The proposition that *every man is tall if Venus is bright* seems to be a ‘molecular’ compound of categorical propositions; the same complex proposition is presumably indicated by ‘if Venus is bright then every man is tall’. The proposition that *not only every man is tall* apparently extends a categorical proposition, via the elements indicated by ‘not’ and ‘only’. Such reflections suggest the possibility, explored with great ingenuity by medieval logicians, that all propositions are composed of categorical propositions and a small number of logical (or so-called syncategorematic) elements. This is not to say that all propositions were, or could be, analyzed in this manner. But by formulating various Aristotelian inference schemata, in ways that complemented proposed analyses of complex propositions, many impeccable infererences were revealed as instances of valid syllogistic forms.

Medieval logicians also discussed the relation of logic to grammar. Many viewed their project, in part, as an attempt to uncover principles of a mental language common to all thinkers. (Aristotle had said that spoken sounds symbolize ‘affections of the soul’.) From this perspective, one expects a few differences between the logical forms of propositions, and overt features of sentences. Spoken languages must mask certain aspects of logical structure, if the proposition that *every man swam* has categorical form3and thus contains a copula. Ockham held that a mental language would have no need for Latin's declensions, and that logicians could ignore such aspects of spoken language. The ancient Greeks were aware of sophisms like: that dog is a father, and that dog is yours; so that dog is your father. This bad inference cannot share its form with the superficially parallel (but impeccable) variant: that dog is a mutt, and that mutt is yours; so that dog is your mutt. So the superficial features of sentences are not infallible guides to the logical forms of propositions. But the divergence was held to be relatively minor. Spoken sentences have structure; they are composed, in systematic ways, of words. And the assumption was that sentences reflect the major aspects of logical form, including subject-predicate structure. There is a distinction between logic and the task of describing the sentences used in spoken languages. But the connection between logic and grammar was thought to run deep, making it tempting to say that the logical form of a proposition is the grammatical form of some (perhaps mental) sentence.

3. Motivations for Revision

Towards the end of the eighteenth century, Kant could say (without much exaggeration) that logic had followed a single path since its inception, and that ‘since Aristotle it has not had to retrace a single step’. He also said that syllogistic logic was ‘to all appearance complete and perfect’; but this was exuberance. There were too few schemata, yet there were also too many.

Some valid schemata are reducible to others, in that any inference of the reducible form can be revealed as valid (with a little work) given other schemata. And this turns out to be important. Consider

(9) If Al ran then either Al did not run or Bob did not swim, and Al ran; so Bob did not swim.

And assume that ‘Al did not run’ negates ‘Al ran’, while ‘Bob did not swim’ negates ‘Bob swam’. Then (9) is an instance of ‘if **A** then either not-**A** or not-**B**, and **A**; so not-**B**’. But we can treat this as a derived form, reducible to other valid schemata, like ‘if **the first** then **the second**, and **the first**; so **the second**’. Given the premises of (9), it follows that either not-**A** or not-**B**; so given **A**, it follows that not-**B**, in accordance with the schema ‘either not **the first** or not **the second**, and **the first**; so not **the second**’. Similarly, as Aristotelian logicians recognized, the following schema can be treated as a derived form:

(10) Some *P* is not *D*, and every *S* is *D*; so not every *P* is an *S*.

We have already seen that if some *P* is not *D*, then not every *P* is *D*; and every *P* is *D*, if both every *S* is *D* and every *P* is an *S*. So it cannot be that both of these conditions obtain, given the first premise of (10); and if every *S* is *D*, as stated in the second premise, then it follows that not every *P* is an *S*.

This invites the thought that further reduction is possible, especially given another respect in which there are more syllogistic schemata than one would like. Consider the contribution indicated by ‘every’ to propositions of the form: every *P* is *D*; not every *P* is *D*; every *P* is not *D*, etc. Ideally, one would specify this contribution--the logical role of the universal quantifer--with a single schema that reveals a *common* contribution to all propositions containing a universal quantifier. Similarly, one would like to characterize the common contribution of negation to propositions of diverse forms: not **A**; not every *P* is *D*; some *P* is not *D*; not both **A** and **B**; etc. But syllogistic logic is not ideal in this respect.

Correspondingly, one might suspect that there are relatively few *basic* inferential patterns. Some inferences may reflect inherently compelling transitions in thought. Perhaps ‘**B** if **A**, and **A**; so **B**’ is so obvious that logicians are entitled to take this rule of inference as axiomatic. But how many rules are plausibly regarded as fundamental in this sense? Theoretical elegance and explanatory depth favor theories with fewer irreducible assumptions. Indeed, Euclid's geometry had long provided a model for how to present a body of knowledge as a network of propositions that follow from a few basic axioms; and for several reasons, foundational questions played an important role in nineteenth century logic and mathematics. The work of Boole and others showed that progress in this regard was possible with respect to the logic of inferences involving propositional variables. But the syllogisms remained disunified and incomplete, for reasons related to another failing of traditional logic/grammar.

Propositions involving *relations*--e.g., the proposition that Juliet kissed Romeo--are evidently not categorical. One might suggest ‘Juliet was a kisser of Romeo’ as an overtly categorical paraphrase. But the predicate ‘kisser of Romeo’ differs, in ways that matter to inference, from predicates like ‘woman’. If some kisser of Romeo died, it follows that someone was kissed; whereas the proposition that some woman died has no comparable consequence (stated in the passive voice). Correlatively, if Juliet kissed Romeo, then Juliet kissed *someone*. This last proposition is of interest, even if we express it by saying

'Juliet was a kisser of Romeo'; for such a proposition involves a quantifier (outside the subject) as part of a complex predicate. And traditional logic does not provide the resources needed for capturing the validity of inferences whose validity depends on quantifiers *within* predicates, as in:

(11) Some patient respects some doctor, and every doctor is a sailor; so some patient respects some sailor.

If 'respects some doctor' and 'respects some sailor' are nonrelational, like 'is tall', (11) has the following form:

Some *P* is *T*, and every *D* is an *S*; so some *P* is *O*.

(Replacing '*T*' with 'a respecter of some doctor' and '*O*' with 'a respecter of some sailor'.) But this schema, which fails to reflect any quantificational structure in the *predicates*, is not valid. Its instances include the bad inference: some patient is tall, and every doctor is a sailor; so some patient is omniscient. This dramatizes the point that 'respects some doctor' and 'respects some sailor' are logically related, in ways that 'is tall' and 'is omniscient' are not.

One can introduce a variable '$\underline{R}$', intended to range over relations, and formulate the following schema: some *P* $\underline{R}$ some *D*, and every *D* is an *S*; so some *P* $\underline{R}$ some *S*. But the problem remains. Quantifiers can still appear in the predicates, as in the following (complex, but still impeccable) inference:

(12) Every patient who met every doctor is tall, and some patient who met every doctor respects every senator; so some patient who respects every senator is tall.

If 'patient who met every doctor' and 'patient who respects every senator' are nonrelational, then (12) has the form: every *P* is *T*, and some *P* $\underline{R}$ every *S*; so some *O* is *T*. And this is not a valid form. Consider: every politician is tall, and some politician respects every senator; so some obstetrician is tall. Again, one might abstract a valid schema that covers (12), letting parentheses indicate a relative clause:

Every $P(\underline{R}_1$ every $D)$ is T, and some $P(\underline{R}_1$ every $D)$ $\underline{R}_2$ every S; so some $P(\underline{R}_2$ every $S)$ is T.

But there can be still further quantificational structure in these predicates; and so on. This suggests that it really is important--if impeccability is to be revealed as a matter of form--to find a *general* characterization of how quantifiers contribute to propositions in which quantifiers can appear.

4. Frege and Formal Language

Frege showed how to resolve these difficulties in one fell swoop. His system of logic, published in 1879 (and still in use, with notational modifications), was the single greatest contribution to the subject. So it is

significant that on Frege's view, propositions do not have the subject-predicate form of sentences. Frege's achievement required a substantial distinction between logical form and grammatical form (as traditionally conceived). It is hard to overemphasize the impact of this point on subsequent discussions of thought and its relation to language.

Frege's leading idea was that propositions have 'function-argument' structure. The intended analogy to mathematical functions, developed by Frege in later work, intimates his view. The successor function maps every integer onto its successor; it maps the number 1 onto the number 2, 2 onto 3, etc. We can represent this function, using a variable that ranges over integers, as follows: $S(x) = x + 1$. As this notation makes clear, the function takes integers as *arguments*; and given an argument, the *value* of the function is the successor of that argument. The division function, representable as '$Q(y, z) = y/z$', maps *ordered pairs* of numbers onto quotients; the pair (8, 4) onto 2; (9, 3) onto 3; etc. Mappings can also be conditional, as with the function that maps every even integer onto itself and odd integer onto its successor: $F(x) = x$ if x is even, and $x + 1$ otherwise. By itself, however, no function has a value. Frege says that functions are *saturated* by arguments. The metaphor, encouraged by his claim that we can indicate functions with expressions like 'S( ) = ( ) + 1', is that a function has 'holes' that can be 'filled' by arguments (of the right sort). Variable letters, such as the '*y*' and '*z*' in as '$Q(y, z) = y/z$', are convenient for representing functions that take more than one argument. But we could also express the division function by indexing the argument places as follows:

$$Q([_]_i , [_]_j) = [_]_i / [_]_j$$

Similarly, propositions are said to contain unsaturated elements in combination with the requisite number of arguments. The proposition that Mary sang is said to contain a functional component indicated by 'sang', and an argument indicated by 'Mary': Sang(Mary). Frege thinks of the relevant function as a conditional mapping from individuals to truth values: Sang(x) = *true* if x sang, and *false* otherwise. The proposition that John admired Mary contains an ordered pair of arguments and a function: Admired(John, Mary). One can think of the function as a mapping from ordered pairs of individuals to truth values--or alternatively, as a function from individuals to *functions* from individuals to truth values. In any case, the proposition that Mary was admired by John has the same function-argument structure; although pace Frege, this is not yet reason to deny that all propositions have subject-predicate structure. (A traditional grammarian could say that the passive sentence fails to reflect the true structure of the indicated proposition, in which the subject is John, the first argument.) But Frege's treatment of quantified propositions, which flows from his claims about saturation, does depart from the tradition.

Let ***F*** be the function indicated by 'Sang( )'. Mary sang, if and only if: ***F*** maps the individual Mary onto the value *true*; i.e., ***F*** has the value *true* given Mary as argument. If Mary (or anyone else) sang, then someone sang. Thus, someone sang if and only if ***F*** maps at least one individual onto the value true; or using a modern variant of Frege's notation, $\exists x$[Sang(x)]. The quantifier '$\exists x$' is said to bind the variable '*x*', which appears in 'Sang(x)'; and this variable ranges over objects in a domain of discourse. (For now, assume the domain contains only persons.) If everyone sang, then each individual in the domain sang, so ***F*** maps each individual on the value *true*; or using formal notation, $\forall x$[Sang(x)]. A quantifier binds each

occurrence of its variable, as in '$\exists x[D(x)$ & $C(x)]$', which reflects the logical form of 'someone is deceitful and clever'. Here the quantifier combines with a conjunction of functions:

$$[\text{Quantifier}]_i\ [\ \text{Predicate}([_]_i)\ \&\ \text{Predicate}([_]_i)\ ]$$

Turning now to the syllogistic proposition that some politician is deceitful, traditional grammar suggests the division 'some politician / is deceitful', with the noun 'politician' going with 'some'. Frege suggests, however, that the logically relevant division is between the quantifier and the rest: $\exists x[P(x)$ & $D(x)]$; someone is both a politician and deceitful. (If the logical form is '$\exists x[P(x)$? $D(x)]$', where '?' is a connective, then '&' is the connective we want; some politician is deceitful, if and only if someone is both a politican and deceitful.) With respect to the proposition that every politician is deceitful, Frege thinks the logical form is given by '$\forall x[P(x) \rightarrow D(x)]$': everyone is such that if he is a politician then is deceitful. (Clearly, '$\forall x[P(x)$ & $D(x)]$' would be wrong, since this implies that everyone is a politician. Frege defines '$\rightarrow$' so that '$\forall x[P(x) \rightarrow D(x)]$' is equivalent to '$\forall x[\neg P(x) \vee D(x)]$', everyone either fails to be a politician or is deceitful; and '$\forall$' is defined so that $\forall x[P(x)] \leftrightarrow \neg\exists x[\neg P(x)]$.) This notation suggests that grammar is misleading in at least two respects. First, grammar leads us to think that 'some politician' indicates a major *constituent* of the proposition that some politician is deceitful. But if Frege is right, no constituent of the *proposition* contains both the quantifier and the predicate indicated by 'politician'; quantified propositions divide along lines that keep the predicates together (apart from the quantifier). Second, grammar masks a difference between existential and universal syllogistic propositions: the main predicates are related conjunctively in the former, and conditionally in the latter. Initially, one might object to Frege's departure from intuition here; but on his view, multiply quantified propositions present no special difficulty.

Just as a single quantifier can bind an unsaturated position associated with a function that takes a single argument, two quantifiers can bind two unsaturated positions associated with a function that takes a pair of arguments. The proposition that everyone trusts everyone, for example, has the following (noncategorical) form: $\forall x \forall y[T(x,y)]$. Assuming that 'John' and 'Mary' indicate arguments, it follows that John trusts everyone, and that everyone trusts Mary--i.e., $\forall y[T(j,y)]$ and $\forall x[T(x,m)]$. It follows from all three propositions that John trusts Mary: $T(j,m)$. Frege's rule of inference, which captures the key logical role of the universal quantifier, is that one can replace a variable bound by a universal quantifier with a name for some individual in the domain. Similarly, one can replace a name with a variable bound by an existential quantifier. (Schematically: $\forall x(...x...)$, therefore $...n...$; and $...n...$, therefore $\exists x(....x....)$. Given $T(j,m)$, it follows that someone trusts Mary and that John trusts someone: $\exists x[T(x, m)]$; and $\exists x[T(j,x)]$. It follows from all three propositions that someone trusts someone: $\exists x \exists y[T(x,y)]$. (A single quantifier can bind multiple argument positions, as in '$\exists x[T(x,x)]$'; but this means that someone trusts herself.)

Mixed quantification introduces an interesting wrinkle. The propositions indicated by '$\exists x \forall y[T(x,y)]$' and '$\forall y \exists x[T(x,y)]$' differ. We can paraphrase the first as 'there is someone who trusts everyone' and the second as 'everyone is trusted by someone or other'; the second follows from the first, but not *vice versa*. This raises the possibility that 'someone trusts everyone' is *ambiguous*--that it can indicate either of two propositions. (Although this in turn raises difficult questions about what natural language expressions

are, and what it is for an expression to indicate a proposition. But for Frege, the important point was the distinction between the propositions--or *thoughts*, as he often called them. Similar remarks apply to '$\forall x \exists y[T(x,y)]$' and '$\exists y \forall x[T(x,y)]$'.) A related phenomenon is exhibited by 'John danced if Mary sang and Chris slept'. Is the indicated proposition of the form '(**A** if **B**) and **C**' or '**A** if (**B** and **C**)'? Is someone who says 'The artist drew a club' talking about a sketch or a card game? One can use 'is' to express identity, as in 'Hesperus is the planet Venus'; but in 'Venus is bright', 'is' indicates predication. In 'Venus is a planet', 'a' is logically inert; yet in 'John saw a planet', 'a' indicates existential quantification: $\exists x[P(x) \& S(j,x)]$. (Rendering 'Venus is a planet' as '$\exists x[P(x) \& x = v]$' treats 'is a planet' differently than 'is bright' by appealing, unnecessarily, to quantification and identity.)

According to Frege, such ambiguities provide further evidence that natural language is not ideally suited to the task of representing propositions and inferential relations *perspicuously*, and he wanted a language that was up to the task. (Leibniz and others had envisioned a 'Characteristica Universalis', but without suggestions for how to proceed beyond syllogistic logic in creating one; and given Frege's interest in the foundations of arithmetic, he was especially interested in claims, like 'every number has a successor'.) This is not to say that natural language is ill-suited for other purposes, like communication, or that natural language is useless as a tool for representing propositions. Rather, Frege suggested that natural language is like the eye, whereas a good formal language is like a microscope that reveals structure not otherwise observable.

5. Descriptions and Analysis

Frege did not distinguish--or at least did not emphasize any distinction between--names like 'John' and descriptions like 'the boy' or 'the tall boy in the garden'. Initially, both kinds of expression appear to indicate arguments, as opposed to functions; so one might think that the propositional contribution of 'the...', whatever its syntactic complexity, is just the individual that satisfies the description. On this view, the logical form of 'the boy sang' is 'Sang(*b*)', where '*b*' is a an unstructured symbol that designates the boy in question. But this makes syntactic elements of the description logically irrelevant, and this seems wrong. If the boy sang, it follows that some boy sang; if the tall boy in the garden sang, some tall boy sang. Moreover, 'the' implies *uniqueness* in a way that 'some' does not. One can say 'the boy sang' without denying that universe contains a plurality of boys, but one implies that there is exactly one contextually relevant boy.

In general, if the *P* is *D*, it follows that some *P* is *D*, and that there is only one (relevant) *P*. Or put another way: there is a *P*, and there is at most one *P*, and it is *D*. Russell held that the logical form of 'the boy sang' reflects these implications: $\exists x\{\text{Boy}(x) \& \forall y[\text{Boy}(y) \leftrightarrow x = y] \& \text{Sang}(x)\}$. The middle conjunct was Russell's way of expressing uniqueness; given an object *x*, '$\forall y[\text{Boy}(y) \leftrightarrow x = y)]$' says that everything is such that it is a boy if and only if it is identical with *x*. But however one formulates the middle conjunct, 'the boy' does not correspond to any constituent of Russell's formalism. This reflects his main point: while a speaker may refer to a boy in saying 'the boy sang', the boy is not a constituent of the proposition indicated. The proposition has the form of an existential quantification with a bound variable; it does *not* have the form of a function saturated by an argument--the boy referred to. In this respect, 'the

boy' is like 'some boy'; but not even 'the' indicates a constituent on Russell's view.

Natural language can thus mislead us about the constituency of the propositions we assert. Russell went on to apply this point to a now famous puzzle. Even though France is kingless, 'the king of France is bald' indicates a proposition; the sentence is not, in that sense, meaningless. If the proposition consists of the function indicated by 'Bald( )' and an argument indicated by 'the king of France', there must be an argument so indicated. But what is it? Appeal to nonexistent kings is, to say the least, dubious. Russell concluded that 'the King of France is bald' indicates a quantified proposition: $\exists x\{K(x) \,\&\, \forall y[K(y) \leftrightarrow x = y] \,\&\, B(x)\}$. And one should not be led into thinking otherwise by the following spurious reasoning: every proposition is true or false; so the king of France is bald or not; so there is a present king of France (somewhere), and he is either bald or not. For let '¶' stand for the proposition that the king of France is bald. Russell grants that ¶ is true or false. In fact, it is false, since there is no king of France; given $\neg\exists x[K(x)]$, it follows that $\neg\exists x\{K(x) \,\&\, \forall y[K(y) \leftrightarrow x = y] \,\&\, B(x)\}$. But it hardly follows that there is a king of France who is either bald or not. Russell thinks the confusion lies in a failure to distinguish the negation of ¶ from: $\exists x\{K(x) \,\&\, \forall y[K(y) \leftrightarrow x = y] \,\&\, \neg B(x)\}$; the king of France is not bald. And the natural language expression 'the king of France is bald or not' fosters such a confusion.

The idea that philosophical puzzles might *dissolve*, if only we understood the logical forms of our claims, attracted copious attention. Wittgenstein argued, in his influential *Tractatus Logico-Philosophicus*, that: (i) the very possibility of meaningful sentences, which can be true or false depending on how the world is, requires propositions with structures of the sort Frege and Russell were getting at; (ii) all propositions are logical compounds of--and thus analyzable into--atomic propositions that are inferentially independent of one another, though even simple natural language sentences may indicate complex propositions; and (iii) the right analyses would, given a little reflection, reveal all philosophical puzzles as confusions about how language is related to the world. Russell never endorsed (iii). But for reasons related to epistemological puzzles, Russell held that we are *directly acquainted* with the constituents of those propositions into which every proposition (that we can grasp) can be analyzed; we are not directly acquainted with mind-independent objects that cause our various sensory perceptions; and so the apparent referents of proper names (in natural language) are not constituents of basic propositions.

This led Russell to say that such names are disguised descriptions. On this view, 'Venus' is associated with a (perhaps complex) predicate, and 'Venus is bright' indicates a proposition of the form: $\exists x\{V(x) \,\&\, \forall y[V(y) \leftrightarrow x = y] \,\&\, B(x)\}$. This has the tendentious consequence that for some predicate 'V', it follows that $\exists x[V(x)]$, if Venus is bright; though perhaps, *pace* Russell, 3V' is an unanalyzable predicate true of exactly one mind-indepedent planet. (A related view is that 'Venus is bright' shares its logical form, not with 'The nearest planet is bright', but with '*That* planet is bright'.)

Questions about names are related to psychological reports, like 'Mary thinks Venus is bright', which present puzzles of their own. At least intially, such reports seem to indicate propositions that are neither atomic nor *logical* compounds of simpler propositions; and as Frege noted in a famous paper, it seems that replacing one name with another name for the same object can affect the truth of a psychological report. If Mary fails to know that Hesperus *is* Venus, she might think Venus is a planet without thinking

Hesperus is a planet; yet any function that has the value *true* given Venus as argument has the value *true* given Hesperus as argument. So unsurprisingly, Frege, Russell, and Wittgenstein all held--in varying ways--that psychological reports are misleading with respect to their logical form, since intuitively coreferential names can be associated with distinct propositional contributions. (Wittgenstein later noted that claims like ‘This is red’ and ‘This is yellow’ present difficulties for his view: if the indicated propositions are unanalyzable, and thus logically independent, each should be compatible with the other; yet it is hard to envision any analysis that accounts for the apparent impeccabilty of ‘This is red, so this is not yellow’. This raises questions about whether *all* inferential security is due to logical form.)

6. Restricted Quantifiers

Within the Frege-Russell-Wittgenstein tradition, which flourished in England and America, it became a commonplace that logical form and grammatical form often diverge--even if the most ambitious analytic projects did not succeed. But recent work on quantifiers suggests that the divergence may have been exaggerated, because of how the idea of variable-binding was implemented. Consider again the proposition that some boy sang, and the proposed logical division into the quantifier and the rest:

> $\exists x$[Boy(x) & Sang(x)];
> For some x, x is a boy and x sang.

While this captures the truth conditions of the English sentence, one can also offer a ‘logical paraphrase’ that more closely parallels the grammatical division ‘some boy / sang’: for some x such that x is a boy, x sang. One can formalize this alternative, by using *restricted* quantifiers, which (as the terminology suggests) incorporate a restriction on the domain over which the variable in question ranges. For example, ‘$\exists x$:Boy(x)’ is an existential quantifier that binds a variable ranging over boys in the unrestricted domain. So ‘$\exists x$:Boy(x)[Sang(x)]’ is interpreted as: for some x such that Boy(x), x sang; that is, some (individual who is a) boy sang. This is logically equivalent to ‘$\exists x$[Boy(x) & Sang(x)]’.

Universal quantifiers can also be restricted, as in ‘$\forall x$:Boy(x)[Sang(x)]’, which is interpreted as follows: for every x such that Boy(x), x sang; that is, every (individual who is a) boy sang. This is logically equivalent to ‘$\forall x$[Boy(x) $\rightarrow$ Sang(x)]’; although one might well think the inferential difference between ‘some boy sang’ and ‘every boy sang’ lies entirely with the propositional contributions of ‘some’ and ‘every’--and not (in part) with the contribution of alleged connectives between predicates. Restrictors can be logically complex, as in ‘Some tall boy sang’ or ‘Some boy who respects Mary sang’, which are rendered as ‘$\exists x$:Tall(x) & Boy(x)[Sang(x)]’ and ‘$\exists x$:Boy(x) & Respects(x, mary)[Sang(x)]’.

From this perspective, words like ‘someone’, and the grammatical requirement that ‘every’ be followed by a noun (like ‘boy’), reflect the form of those quantifiers that figure in propositions indicated by natural language sentences. Such quantifiers are composed of a *determiner*, indicated by words like ‘some’ and ‘every’, and a (restricting) predicate that is true of individuals of some sort. One can think of determiners as functions from ordered pairs of predicates to truth values--or equivalently, as functions *from* predicates *to* functions from predicates to truth values. This makes explicit that ‘every’ and ‘some’ indicate relations

between predicates, much as transitive verbs express relations between individuals.

Since ‘*x*’ and ‘*y*’ are variables ranging over individuals, one can say that the function indicated by the transitive verb ‘loves’ has the value *true* given the ordered pair <*x*,*y*> as argument if and only if *x* loves *y*. In this notational scheme, ‘*y*’ corresponds to the direct object (or *internal* argument), which combines with the verb to form a complex predicate (like ‘loves Chris’); ‘*x*’ corresponds to the grammatical subject (or *external* argument) of the verb. If we think about ‘every boy sang’ analogously, ‘boy’ is the internal argument with which ‘every’ combines to form a phrase. We can now introduce ‘*X*’ and ‘*Y*’ as variables ranging over functions from individuals to truth values, stipulating that the *extension* of such a function is the set of things that the function maps onto the value *true*. Then one can say that the function indicated by ‘every’ has the value *true* given the ordered pair <*X*, *Y*> as argument if and only if the extension of *X* includes the extension of *Y*. Similarly, the function indicated by ‘some’ has the value *true* given the ordered pair <*X*, *Y*> as argument if and only if the extension of *X* intersects with the extension of *Y*. At this point, we no longer need the symbols ‘∃’ and ‘∀’. For we can say that ‘Every:Boy(*x*)[Sang(*x*)]’ is true if and only if the singers included the boys; and ‘Some:Boy(*x*)[Sang(*x*)]’ is true if and only if the singers and the boys intersect. (Moreover, the truth condition for ‘Most boys sang’ cannot be captured with ‘∃’, ‘∀’, and the sentential connectives. But we can say that most boys sang if and only if: the boys who are also singers outnumber the boys who are not singers; or put another way, the number of boys who sang exceeds the number of boys who did not sing. So we can say that ‘most’ indicates a function that takes the value *true* given <*X*, *Y*> as argument if and only if: the number of things that *Y* and *X* both map onto *true* exceeds the number of things that *Y* maps onto *true* but *X* does not.)

The Russellian formula

$$\exists x\{\text{Boy}(x) \,\&\, \forall y[\text{Boy}(y) \rightarrow x = y] \,\&\, \text{Sang}(x)\}$$

can be replaced with

$$\text{Some:Boy}(x)[\text{Sang}(x)] \,\&\, |\text{Boy}| = 1$$

interpreted as follows: for some *x*, *x* a boy, *x* sang; and there is exactly one (relevant) boy. On this view, ‘the boy’ still does not correspond to a constituent of the formalism; nor does ‘the’. But one can also treat ‘the’ as a determiner in its own right, as in

‘The:Boy(*x*)[Sang(*x*)]’,

while specifying the propositional contribution of this determiner as follows:

The <*X*, *Y*> = *true* if |*Y*| = 1 & the extensions of *X* and *Y* intersect, and *false* otherwise.

This version of Russell's theory still preserves his central claim. While there may be a boy one refers to in saying ‘the boy sang’, the boy is not a constituent of the indicated proposition, which is quantificational--

involving two predicates and a logical relation between them. But far from showing that the logical form of ‘the boy sang’ diverges dramatically from its grammatical form, the restricted quantifier notation suggests that the logical form closely parallels the grammatical form.

It is worth noting, briefly, an implication of this point for the inference ‘the boy sang, so some boy sang’. If the logical form of ‘the boy sang’ is

Some:Boy(x)[Sang(*x*)] & |Boy|=1,

then the inference is an instance of the simple schema ‘*A* & *B*; so A’. But if the logical form of ‘the boy sang’ is simply ‘The:Boy(*x*)[Sang(*x*)]’, both premise and conclusion of the inference have the abstract form ‘Determiner:Boy(*x*)[Sang(*x*)]’; in which case, the impeccability of the inference depends on the specific propositional contributions of ‘the’ and ‘some’. (If the validity of an inference depends solely on the propositional contributions of its logical elements, perhaps ‘the’ and ‘some’ indicate logical elements that are inferentially related.)

7. Transformational Grammar

Still, the subject/predicate structures of ‘Mary trusts every doctor’ and ‘Some boy trusts every doctor’ diverge from the logical forms of the indicated propositions. Even with restricted quantifiers, and rewriting ‘*T*(*x*, *y*)’ as ‘(*x*)*T*(*y*)’, the formal sentences ‘Every:Doctor(*y*){(mary)Trusts(*y*)}’ and ‘[Some:Boy(*x*)][Every:Doctor(*y*)]{(*x*)Trusts(*y*)]}’ differ from the spoken English sentences. But in thinking about the relation of logic to grammar, one must not assume a naive conception of the latter. For example, the grammatical form of a sentence need not be determined by the linear order of its words. We can distinguish the logical form ‘(**A** if **B**) and **C**’ from ‘**A** if (**B** and **C**)’. And we can distinguish ‘Mary{saw [the boy (with binoculars)]}’ from ‘Mary{[saw (the boy)](with binoculars)}’; with the former indicating that the boy had binoculars, while the latter indicates that Mary used binoculars to see the boy. Diagnosing ambiguity may be just one among many reasons for positing unobvious grammatical structure. And it turns out that the study of *natural* language suggests a rich conception of grammatical form that diverges from the Aristotelian tradition in just the way that modern quantificational logic does.

A leading idea of modern linguistics is that at least some grammatical structures are *transformations* of other structures; and this is related to the idea that words (and phrases) often appear to be *displaced* from the positions typically associated with the relevant grammatical roles. For example, the word ‘who’ in (13) is associated with the second (direct object) argument position of the verb ‘saw’:

(13) Mary wondered who John saw.

Correspondingly, (13) can be glossed as ‘Mary wondered for which x (x a person) John saw x’. This suggests that (13) reflects a transformation of the ‘deep structure’ (13d) into the ‘surface structure’ (13s):

(13d) Mary wondered [John saw who]

(13s) Mary wondered [who_i [John saw $[_]_i$]]

In (13d), the embedded clause has the same basic form as ‘John saw Bill’; and in (13s), ‘who’ has been displaced from the argument position represented by the blank. Evidently, ‘who’ is also displaced in ‘Who did John see’. (Similar remarks apply to ‘why’, ‘what’, ‘when’, ‘how’, etc.)

One might also explain the synonymy of (14) and (15), by positing a common deep structure, (14d):

(14) John seems to like Mary

(14s) John_i seems ($[_]_i$ to like Mary)

(14d) Seems(John likes Mary)

(15) It seems John likes Mary

Since every English sentence needs a grammatical subject, (14d) must be modified: either by displacing ‘John’, as in (14s); or by inserting a dummy subject ‘it’, which does not indicate an argument, as in (15). (Compare ‘There is something in the garden’, which is synonymous with ‘Something is in the garden’.) Appeal to displacement also lets one distinguish the superficially parallel sentences (16) and (17):

(16) John is easy to please.

(17) John is eager to please

If (16) is true, it is easy (for somone) to please John, and so someone can easily please John; but if (17) is true, John is eager that he please someone or other. This asymmetry is effaced by representations like ‘Easy-to-please(John)’ and ‘Eager-to-please(John)’. But the contrast is made manifest by:

(16s) John_i is easy [*e* to please $[_]_i$]

(17s) John_i is eager [$[_]_i$ to please *e*]

where ‘*e*’ indicates an unvoiced (or empty) argument position. On this view of grammar, the ‘surface subject’ may in fact be the *object* of a verb embedded within the main predicate. Of course, such hypotheses about (hidden) grammatical structure require defense. But Chomsky and others have argued that such hypotheses are needed to account for a range of data concerning human linguistic capacities.

As an illustration of the *kind* of data that is relevant, note that (18-20) are perfectly fine expressions of English, while (21) is word salad.

(18) The boy who sang was happy.

(19) Was the boy who sang happy.

(20) The boy who was happy sang.

(21) *Was the boy who happy sang.

This suggests that the auxiliary verb ‘was’ can be displaced from some positions but not others. That is, while (19s) is a permissible transformation of (18d), (21s) is not a permissible transformation of (20d):

(18d) {The [boy (who sang)]} [was happy]

(19s) Was$_i$ <{the [boy (who sang)]} [[_]$_i$ happy]>

(20d) {The [boy (who <was happy>)]} sang}

(21s) *Was$_i$ <{the [boy (who < [_]$_i$ happy>)]} sang}>

The ill-formedness of (21s) is striking, since one can ask if the boy who was happy sang. One can also ask whether (22) is true. But (23) corresponds to ‘The boy who lost was kept crying’, and *not* (22):

(22) The boy who was lost kept crying.

(23) Was the boy who lost kept crying.

This is precisely what one would expect, if ‘was’ cannot be displaced from its position in (22):

*Was$_i$ <{the [boy (who [_]$_i$ lost)]} [kept crying]}>

Such explanations appeal to nonobvious grammatical structure, and constraints on transformations. (For example, no ‘fronting’ an auxiliary verb from an embedded clause.) A sentence was thus said to have a deep structure (DS), which reflects Fregean function-argument stucture, as well as a surface structure (SS); and linguists posited various constraints on DS, SS, and the transformations that relate them. But as the theory was elaborated and refined under empirical pressure, linguists concluded that DS and SS failed to reflect all the grammatically relevant features of sentences. It was argued that another level of grammatical structure, obtained by an operation on SS, was needed to account for certain linguistic facts. The hypothesized transformation, called *quantifier raising* because it targeted the kinds of expressions that indicate (restricted) quantifiers, mapped structures like (24s) onto structures like (24LF).

(24s) {(some boy) [trusts (every doctor)]}.

(24LF) [some boy]$_i$[every doctor]$_j${ [_]$_i$ [trusts [_]$_j$]}

Clearly, (24LF) does not reflect the pronounced word order in English. But the idea is that (24s) can determine the pronounced form of the sentence, while also serving as input to the new transformation. The label ‘LF’ (intimating ‘logical form’) was used for a *grammatical* structure, since the *scope* of a

natural language quantifier is determined by its position at LF--and not by its position at DS or SS. Moreover, the mapping between (24LF) and the following logical formalism is trivial:

[some:boy(*x*)][every:doctor(*y*)]{Trusts(*x*,*y*)}

And (24LF) differs from another structure, interpreted as:

[every:doctor(*y*)][some:boy(*x*)]{Trusts(*x*,*y*)}.

[every doctor]$_i$[some boy]$_j${ [_]$_j$ [trusts [_]$_i$]}

There is a large body of work suggesting that many logical properties of quantifiers, names, and pronouns are similarly reflected in properties of LF. To take just one example, if (25) is true, it follows that some doctor treated some doctor; whereas (26) does not have this consequence:

(25) Every boy saw the doctor who treated himself.
(26) Every boy saw the doctor who treated him.

The truth conditions of (25-26) seem to be (respectively):

[every:boy(*x*)][the:doctor(*y*) & treated(*y*,*y*)]{saw(*x*, *y*)]}

[every:boy(*x*)][the:doctor(*y*) & treated(*y*,*x*)]{saw(*x*, *y*)}

This suggests that ‘himself’ is behaving like a variable bound by ‘the doctor’, while ‘every boy’ can bind ‘him’. And there are independent grammatical reasons for saying that ‘himself’ must be linked to ‘the doctor’, while ‘him’ must not be so linked:

Every boy saw [the doctor]$_i$ who treated [himself]$_i$
*[Every boy]$_i$ saw the doctor who treated [himself]$_i$

[Every boy]$_i$ saw the doctor who treated [him]$_i$
*Every boy saw [the doctor]$_i$ who treated [him]$_i$

While there is a conceptual distinction between LF and the traditional notion of logical form, perhaps the LF of a sentence is at least isomorphic to the logical form of the indicated proposition. (If so, one might avoid certain questions prompted by Frege's view of natural language. How can a sentence indicate a proposition with a *different* structure? And if grammar is deeply misleading, why think our intuitions of (im)peccability provide *reliable* evidence about which propositions follow from which?

8. Semantic Structure and Events

The notion of logical form has also played a significant role in theories of meaning for natural languages. One would like to show how the meaning of a complex expression depends on (i) the meanings of its constituents, and (ii) the ways in which the constituents are arranged. It seems that ‘every tall sailor respects some doctor’ and ‘some short boy likes every politician’ exhibits a common mode of semantic combination; and the meaning of each sentence is presumably fixed by this mode of combination, given the relevant word meanings. This claim is sometimes expressed as follows: the meaning of a sentence is determined by its logical form and the meanings of its parts. This assumes that sentences, like propositions, have logical forms. But in so far as grammatical form mirrors logical form, one might say that the meaning of a sentence S is determined by S's grammatical form and the meanings of its words. (Indeed, some theorists identify the logical form of a sentence with its semantic structure3the way in which its parts are arranged so as to create a complex whose meaning is determined compositionally; and some identify grammatical form with LF, especially in light of Chomsky's recent work, which eschews constraints on DS and SS in favor of constraints on the generation of LFs.)

Davidson and others have urged a version of this idea that draws on Tarski's development of Frege's work. Tarski showed how to provide finitely statable interpretations for certain formal languages, which generate arbitrarily many sentences, by employing recursive rules that assign semantic values to every expression of the language given assignments of semantic values to primitive elements of the language. (This is related to the idea that an inference is valid if and only if: every interpretation that makes the premises true makes the conclusion true, holding fixed the interpretations of logical elements like ‘if’ and ‘every’.) Davidsonians try to construct Tarski-style theories that assign truth conditions to natural language sentences, given the extensions of words and the relevant logical forms. For on their view, a sentence S means that p, if a recursive theory of the right sort assigns the following truth conditions to S: *true* if p, and *false* otherwise. (Montague and others have pursued a similar line of thought.)

For present purposes, the details of this program are less important than Davidson's claim that in constructing any such theory of meaning, we should attend to inferential relations like those exhibited in

(27) Juliet kissed Romeo quickly at midnight.

(28) Juliet kissed Romeo quickly.

(29) Juliet kissed Romeo at midnight.

(30) Juliet kissed Romeo.

If (27) is true, so are (28-30); if (28) or (29) is true, so is (30). The inferences seem impeccable. But the function-argument structure of (27) is not obvious. If we represent ‘kissed quickly at midnight’ as a unstructured predicate that takes two arguments, like ‘kissed’ or ‘kicked’, we will represent the inference from (27) to (30) as having the form: $K^*(x,y)$; so $K(x,y)$. But this form is exemplified by the bad inference: Juliet kicked Romeo; so Juliet kissed Romeo. Put another way, if ‘kissed quickly at midnight’ is a logically unstructured binary predicate, then the following claim is an extra (nonlogical) assumption:

if *x* kissed *y* in a certain manner at a certain time, *x* kissed *y*. But this seems like a tautology, not an assumption that introduces epistemic risk. Davidsonians thus hold that the surface appearances of sentences like (27-30) mask semantic structure; in particular, there is hidden quantification over *events*.

The true form of (30) is said to be manifested by the paraphrase ‘there was a kissing of Romeo by Juliet’. One can formalize this proposal in various ways: ∃*e*[Kissing(*e*) & Of(*e*, Romeo) & By(*e*, Juliet)]; or ∃*e*[Kiss(*e*, Juliet, Romeo)], with the verb ‘kiss’ indicating a function that takes three arguments; or

> (30) ∃*e*[Agent(*e*, Juliet) & Kissing(*e*) & Patient(e, Romeo)]

with Juliet and Romeo being explicitly represented as players of certain *roles* in the event--roughly, the doer (Agent) and the done to (Patient). But whatever the notation, adverbs like ‘quickly’ and ‘at midnight’ are said to indicate further features of the event described, as shown below:

> (27a) ∃*e*[Agent(*e*, Juliet) & Kissing(*e*) & Patient(*e*, Romeo) & Quick(*e*) & At-midnight(*e*)]
>
> (28a) ∃*e*[Agent(*e*, Juliet) & Kissing(*e*) & Patient(*e*, Romeo) & Quick(*e*)]
>
> (29a) ∃*e*[Agent(*e*, Juliet) & Kissing(*e*) & Patient(*e*, Romeo) & At-midnight(*e*)]

If this is correct, then the inference from (27) to (30) is an instance of the following valid form:

> $\exists e[A(e, x) \ \& \ K(e) \ \& \ P(e, y) \ \& \ Q(e) \ \& \ M(e)]$,
> therefore $\exists e[A(e, x) \ \& \ K(e) \ \& \ P(e, y)]$

And the other impeccable inferences involving (27-30) are similarly instances of conjunction reduction. If the grammatical form of (30) is simply ‘{Juliet [kissed (Romeo)]}’, then the mapping from grammatical to logical form is not transparent; and the grammar is misleading--or at least not entirely forthcoming--in that no *word* corresponds to the event quantifier. But a growing body of literature (in philosophy and linguistics) suggests that Davidson's proposal captures an important feature of natural language semantics, and that ‘event analyses’ provide a useful framwork for future discussions of logical form.

Bibliography

The following books provide a useful overview of the history and basic subject matter of logic:

- Kneale, W. & Kneale, M. 1962: *The Development of Logic*. Oxford: OUP, reprinted 1984.
- Sainsbury, M. 1991: *Logical Forms*. Oxford: Blackwell.
- Broadie, A. 1987: *Introduction to Medieval Logic*. Oxford: OUP.

Frege's *Begriffschrift* can be found in:

- *From Frege to Gödel*, J. van Heijenoort, ed. Cambridge, MA: Harvard, 1967.

His later work on functions (‘Function and Concept’) and belief ascriptions (‘Sense and Reference’) can be found in:

- *Translations from the Philosophical Writings of Gottlob Frege*, P. Geach & M. Black (trans.), Oxford: Blackwell, 1952.

For these purposes, Russell's most important books are:

- *Introduction to Mathematical Philosophy* (London: George Allen and Unwin, 1919)
- *Our Knowledge of the External World* (New York: Norton, 1929)
- *The Philosophy of Logical Atomism* (La Salle, Ill: Open Court, 1985).

See also the introduction to the latter, by David Pears; and *Russell*, by Mark Sainsbury (London: Routledge & Kegan Paul, 1979). Stephen Neale's *Descriptions* (Cambridge, MA: MIT Press, 1990) is a recent development of Russell's theory. Wittgenstein's *Tractatus Logico-Philosophicus* (London: Routledge & Kegan Paul, 1961) is importantly related to Russell's logical atomism.

Two key articles on restricted quantifiers, and a third reviewing recent work, are:

- Barwise, J. & Cooper, R. 1981: Generalized Quantifiers and Natural Language. *Linguistics and Philosophy* 4: 159-219.
- Higginbotham, J. & May, R. 1981: Questions, Quantifiers, and Crossing. *Linguistic Review* 1: 47-79.

Intrinsic vs. Extrinsic Properties

I have some of my properties purely in virtue of the way I am. (My mass is an example.) I have other properties in virtue of the way I interact with the world. (My weight is an example.) The former are the intrinsic properties, the latter are the extrinsic properties. This seems to be an intuitive enough distinction to grasp, and hence the intuitive distinction has made its way into many discussions in ethics, philosophy of mind, metaphysics and even epistemology. Unfortunately, when we look more closely at the intuitive distinction, we find reason to suspect that it conflates a few related distinctions, and that each of these distinctions is somewhat resistant to analysis.

1. Introduction

The standard way to introduce the distinction between intrinsic and extrinsic properties is by the use of a few platitudes. Stephen Yablo provides perhaps the most succinct version: “You know what an intrinsic property is: it’s a property that a thing has (or lacks) regardless of what may be going on outside of itself.” (1999: 479). David Lewis provides a more comprehensive list of platitudes.

> A sentence or statement or proposition that ascribes intrinsic properties to something is entirely about that thing; whereas an ascription of extrinsic properties to something is not entirely about that thing, though it may well be about some larger whole which includes that thing as part. A thing has its intrinsic properties in virtue of the way that thing itself, and nothing else, is. not so for extrinsic properties, though a thing may well have these in virtue of the way some larger whole is. The intrinsic properties of something depend only on that thing; whereas the extrinsic properties of something may depend, wholly or partly, on something else. If something has an intrinsic property, then so does any perfect

> duplicate of that thing; whereas duplicates situated in different surroundings will differ in their extrinsic properties. (Lewis 1983a: 111-2)

As we shall see, the last claim Lewis makes (that duplicates never differ with respect to intrinsic properties) is somewhat controversial. The other way to introduce the subject matter is by providing examples of paradigmatic intrinsic and extrinsic properties. One half of this task is easy: everyone agrees that being an uncle is extrinsic, as is being six metres from a rhodadendron. The problem with using this method to introduce the distinction is that there is much less agreement about which properties are intrinsic. Lewis has in several places (1983a, 1986a, 1988) insisted that shape properties are intrinsic, but one could hold that an object's shape depends on the curvature of the space in which it is embedded, and this might not even be intrinsic to that space (Nerlich 1979), let alone the object. Lewis also mentions charge and internal structure as being examples of intrinsic properties.

1.1 Philosophical Importance

The distinction between intrinsic and extrinsic properties plays an essential role in stating several interesting philosophical problems. Historically, the most prominent of these has to do with notions of intrinsic value. G. E. Moore (1903: §18) noted that we can make a distinction between things that are good in themselves, or possess intrinsic value, and those that are good as a means to other things. To this day there is still much debate over whether this distinction can be sustained (Feldman 1998, Kagan 1998), and if it can which kinds of things possess intrinsic value (Krebs 1999). In particular, one of the central topics in contemporary environmental ethics is the question of which kinds of things (intelligent beings, conscious beings, living things, species, etc) might have intrinsic value. While this is the oldest (and still most common) use of the intrinsic/extrinsic distinction in philosophy, it has not played much role in the discussions of the distinction in metaphysics, to which we now turn.

As P. T. Geach (1969) noted, the fact that some object *a* is not *F* before an event occurs but is *F* after that event occurs does not mean that the event constitutes, in any deep sense, a change in *a*. To use a well-worn example, at the time of Socrates's death Xanthippe became a widow; that is, she was not a widow before the event of her husband's death, but she was a widow when it ended. Still, though that event constituted (or perhaps was constituted by) a change in Socrates, it did not in itself constitute a change in Xanthippe. Geach noted that we can distinguish between real changes, such as what occurs in Socrates when he dies, from mere changes in which predicates one satisfies, such as occurs in Xanthippe when Socrates dies. The latter he termed 'mere Cambridge' change. There is something of a consensus that an object undergoes real change in an event iff there is some **intrinsic** property they satisfied before the event but not afterwards.

David Lewis (1986a, 1988) built on this point of Geach's to mount an attack on **endurantism**, the theory that objects persist by being wholly located at different times, and that there can be strict identity between an object existing at one time and one existing at another time. Lewis argues that this is inconsistent with the idea that objects undergo real change. If the very same object can be both *F* (at one time) and not *F* (at another), this means that *F*-ness must be a relation to a time, but this means that it is

not an intrinsic property. So any property that an object can change must be extrinsic, so nothing undergoes real change. Lewis says that this argument supports the rival theory of **perdurantism**, which says that objects persist by having different temporal parts at different times. While this argument is controversial (see Haslanger (1989), Johnston (1987) and Lowe (1988) for some responses), it does show how considerations about intrinsicness can resonate within quite different areas of metaphysics.

The other major area where the concept of intrinsicness has been put to work is in stating various supervenience theses. Frank Jackson (1998) defines physicalism in terms of duplication and physical duplication, which are in turn defined in terms of intrinsic properties. This definition builds upon a similar definition offered by Lewis (1983b). Similarly, Jaegwon Kim (1982) defines a mind/body supervenience thesis in terms of intrinsic properties. As Theodore Sider (1993) notes, the simplest way to define the **individualist** theory of mental content that Tyler Burge (1979) attacks is as the claim that the content of a thinker's propositional attitudes supervenes on the intrinsic properties of the thinker. And many **internalist** theories in epistemology are based around the intuition that whether a thinker is justified in believing some proposition supervenes on the intrinsic properties of the thinker.

Though these are the most prominent uses of the intrinsic/extrinsic distinction in philosophy, they by no means exhaust its uses. Many applications of the distinction are cited by I. L. Humberstone (1996), including the following. George Schlesinger (1990) uses the distinction between intrinsic and extrinsic properties to state a non-trivial version of Mill's principle of the uniformity of nature, though Schlesinger gives his distinction a different name. Wlodzimierz Rabinowicz (1979) uses the distinction to formulate principles of universalizability for moral principles and natural laws. And E. J. Khamara (1988) uses a distinction between relational and non-relational properties to state a non-trivial version of the principle of Identity of Indiscernibles.

1.2 Global and Local

Whether a property is intrinsic, and whether some individual that has that property has it intrinsically, are different issues. The property *being square or married* is no doubt an extrinsic property; but it is a property that is had intrinsically by all squares (assuming *being square* is intrinsic). Once we have these two concepts, a 'global' concept of intrinsicness of properties, and a 'local' concept of a particular object being intrinsically such as to possess some property, we might wonder how they are connected. (The names 'global' and 'local' are taken from Humberstone 1996). In particular, we might wonder which of these should be primary in an analysis of intrinsicness.

At first glance, the principles (GTL) and (LTG) seem to connect the two concepts.

> (GTL) If *F* is a (globally) intrinsic property, and *a* is *F*, then *a* is intrinsically *F*

> (LTG) If every *a* that is *F* is intrinsically *F*, then *F* is a (globally) intrinsic property.

(GTL) is undoubtedly true, but (LTG) is more problematic. If the quantifier in it is actualist (i.e. only

ranges over actual objects), then it is clearly false. Let *F* be the property *being square or being inside a golden mountain*. Even if the quantifier is possibilist, it is not clear that (LTG) should be true. For a problematic example, let *F* be the property *being square or being such that the number 21 does not exist*. Every possible object that is *F* is square, and hence intrinsically *F*, but it is not clear that *F* is an intrinsic property. This question (like a few others we will discuss below) turns on the metaphysics of properties. If two properties that are necessarily coextensive are identical (as Lewis believes), or are guaranteed to be alike in whether they are intrinsic or extrinsic (as Sider 1993 argues), then *F* will be intrinsic. If properties can be individuated more finely than this, and if their intrinsicness or otherwise turns on this fine-grained individuation, then maybe *F* is not intrinsic. We will return to this issue in some of the discussions below.

2. Notions of Intrinsicness

Many different distinctions have been called the intrinsic/extrinsic distinction. As J. Michael Dunn (1990) notes, some authors have used ‘intrinsic’ and ‘extrinsic’ to mean ‘essential’ and ‘accidental’. Dunn is surely right in saying that this is a misuse of the terms. A more interesting distinction is noted by Brian Ellis (1991; discussed in Humberstone 1996: 206). Ellis suggests we should distinguish between properties that objects have independently of any outside forces acting on them (what we will call the Ellis-intrinsic properties), and those that they have in virtue of those outside forces (the Ellis-extrinsic properties). For many objects (such as, say, a stretched rubber band) their shape will be dependent on the outside forces acting on them, so their shape will be Ellis-extrinsic. If one is committed to the idea that shapes are intrinsic, one should think this means that the distinction between the Ellis-intrinsic and Ellis-extrinsic properties is not the same as the intrinsic/extrinsic distinction. Such a judgement may seem a little hasty, but in any case we will turn now to distinctions that have received more attention in the philosophical literature.

2.1 Relational vs. Non-Relational Properties

Many writers, especially in the literature on intrinsic value, use ‘relational’ for the opposite of intrinsic. This seems to be a mistake for two reasons. The first reason is that many properties seem to be both be relational and intrinsic. For example, most people have the property *having longer legs than arms*, and indeed seem to have this property intrinsically, even though the property consists in a certain relation being satisfied. Maybe the property is not intrinsic if whether or not something is an arm or a leg is extrinsic, so perhaps this isn’t a conclusive example, but it seems troubling. As Humberstone notes, some might respond by suggesting that a relational property is one such that if an object has it, then it bears some relation to a distinct thing. But this won’t do either. *Not being within a mile of a rhodadendron* is clearly relational, but does not consist in bearing a relation to any distinct individual, as we can see by the fact that a non-rhodadendron all alone in a world can satisfy it.

A larger problem is that it seems *being intrinsic* and *being relational* are properties of two very different kinds of things. Consider again the property *F*, *being square or being such that the number 21 does not*

exist. Assuming (as we do for now) that we can make sense of the relational/non-relational distinction, *F* is a relational property. But *F* is necessarily co-extensive with the property *being square*, which is surely non-relational. So two necessarily co-extensive properties can differ with respect to whether they are relational. We can put this point a few different ways. If any two properties that are necessarily co-extensive are identical, then being relational is not a property of *properties*, but a property of *concepts*, or in any case of some things individuated as finely as Fregean concepts. If we think that intrinsicness is not a property that makes such fine distinctions, then the relational/non-relational and intrinic/extrinsic distinctions are quite different, for they are distinctions between different kinds of things.

2.2 Qualitative vs. Non-Qualitative Properties

As noted above, one of the platitudes Lewis lists when isolating the concept of intrinsicness is that duplicates never differ with respect to their intrinsic properties. Lewis holds a further principle that may not be obvious from the above quote: that any property with respect to which duplicates never differ is intrinsic. Of course, this is only true if the quantifiers in it are interpreted as possibilist. Otherwise the property *having a greater mass than any man that has ever existed* will be intrinsic, since it never differs between actual duplicates. We will assume from now on that all quantifiers are possibilist, unless otherwise noted. And, following Humberstone, we will say that the properties that do not differ between duplicates are the qualitative properties, which is not to say they are not also the intrinsic properties.

Despite this two-way connection between intrinsicness and duplication, we do not yet have an analysis because the relevant concept of duplication can only be (easily) analysed in terms of intrinsic properties. In the next section we will look at the two ways Lewis has attempted to analyse that concept and hence break into the circle. But for now it is worth looking at some results that follow directly from the idea that intrinsic properties are those that do not differ between duplicates.

First, as Humberstone (1996: 227) notes, if this is our definition of intrinsicness, then we can easily analyse local intrinsicness in terms of global intrinsicness. An object *x* is intrinsically *P* iff all its duplicates are *P*, that is, if all objects that have the same (global) intrinsic properties as it does are *P*. And having this concept of local intrinsicness is quite useful, because it lets us explain what is right about an intuitively attractive (though ultimately mistaken) claim about intrinsic properties. Let *P* be an intrinsic property and *Q* a property such that an object's having *Q* is entailed by its having *P*. One might think in those circumstances that *Q* would be intrinsic, since its possession follows from a fact solely about the object in question, namely that it is *P*. This isn't right in general; to see why let *P* be the property of *being square* and *Q* be the property *being square or being inside a golden mountain*. For some objects that are *Q* their *Q*-ness follows from facts solely about the object, but for others it follows from facts quite extrinsic to the object in question. But, Humberstone notes, something similar is true. If *x* possess *P* intrinsically, and being *P* entails being *Q*, then *x* possesses *Q* intrinsically. This local concept of intrinsicness might also do philosophical work; presumably the intrinsic value of an object depends on which properties it intrinsically possesses, not on which intrinsic properties it possesses.

Secondly, it follows from the definition that necessarily co-extensive properties are alike in being

intrinsic or not. In particular, any property that every possible object has, such as *being such that the number 21 exists*, will be an intrinsic property. Robert Francescotti (1999) takes this to be a decisive mark against Lewis's theory, but others (e.g. Sider 1993, Weatherson 2001) have been willing to treat it as a philosophical discovery. It is crucial to the proof that Lewis's theory entails that this property is intrinsic that the quantifiers in the theory are possibilist. If we let the quantifiers range over the right kind of impossibilities (such as the situations of Barwise and Perry 1983, or the impossible worlds of Nolan 1997) then one can have duplicates that, for example, differ with respect to whether the number 21 exists. Since this approach has not been developed in any detail it is impossible to say at this time whether it would have serious untoward consequences.

Thirdly, the duplication relation is transitive, so any duplicate of a duplicate of David Lewis, is a duplicate of David Lewis. That means that *being a duplicate of David Lewis* is an intrinsic property of all those objects. While this might plausibly be a property that Lewis intrinsically possesses, it is somewhat surprising that it is intrinsic to all of his duplicates. Dunn (1990) reports that Lewis in conversation said that this property (being a duplicate of David Lewis) is equivalent to an infinite conjunction of intrinsic properties (the ones Lewis has) so it should turn out to be intrinsic.

Conversely, assuming the metaphysics of counterpart theory, none of these duplicates of David Lewis is David Lewis himself, so the property *being (identical with) David Lewis* turns out to be extrinsic on this account. Even if we drop the counterpart theory, and allow that objects in different worlds might be strictly identical, still not all duplicates of Lewis will be identical with Lewis, so the property *being (identical with) David Lewis* will still not be intrinsic. It might seem rather odd that a property so internal to Lewis should not be intrinsic. Yablo (1999) notes that in some cases, such as this one, we can make an argument for identity properties not being intrinsic. If it is essential to David Lewis that he be descended from a particular zygote Z, then the fact that something is David Lewis entails that something else is a zygote, and any property whose possession entails the existence of other objects is usually held to be extrinsic. Still, Yablo argues, it is very plausible that the identity properties of some things (especially atoms) should be intrinsic.

Finally, we can define relative notions of duplication, and hence relative notions of intrinsicness (Humberstone 1996: 238). To give just one interesting example, say that a property is nomically intrinsic iff it never differs between duplicates in worlds with the same laws. Then many dispositional properties might turn out to be nomically intrinsic, capturing nicely the idea that they are in a sense internal to the objects that possess them, while their manifestation depends both on external facts, and on the laws being a certain way.

2.3 Interior vs. Exterior Properties

J. Michael Dunn (1990) suggests that odd consequences of Lewis's theory are sufficient to look for a new concept of intrinsicness. He suggests that the notion of intrinsicness is governed by platitudes like the following. "Metaphysically, an *intrinsic* property of an object is a property that the object has by virtue of itself, depending on no other thing. Epistemologically, an intrinsic property would be a property

that one could determine by inspection of the object itself - in particular, for a physical object, one would not have to look outside its region of space-time" (1990: 178) As Dunn notes, the metaphysical definition here is the central one, the epistemological platitude is at best a heuristic. On this view, *being identical to X* will be intrinsic (except in cases where *X* has essential properties rooted outside itself), while *being a duplicate of X* will not be. Also, *having X as a part* will be intrinsic, though it is not on Lewis's account.

Dunn argues that the appropriate logic in which to formulate claims of intrinsicness and to investigate what consequences they have is the relevant logic **R**, and he provides some of the details of how this should be done. But until we see a specific formulation of the idea (comparable in specificity to the accounts of Peter Vallentyne and Stephen Yablo, discussed below in section 3.3), we cannot comment on its consequences. Still, there is an intuitive distinction here, and it clearly differs from the distinction Lewis discusses.

2.4 Which is the real distinction?

If we grasp the three distinctions discussed above, we might well ask which of them is the intrinsic/extrinsic distinction? It is possible that this question has no determinate answer. Humberstone suggests that we have three interesting distinctions here, each of which can do some philosophical work, and there is not much interest in the issue of which of them is called the distinction between intrinsic and extrinsic properties. If we do decide to investigate this seriously, we should perhaps be prepared to be disappointed - there is no guarantee that there will be a fact of the matter which distinction the words 'intrinsic' and 'extrinsic' latch onto.

Should we just give up on identifying *the* intrinsic/extrinsic distinction; then, on pain of having some indeterminacy in our philosophical theories, we must reformulate the theories that are framed using this distinction, specifying which distinction should take the role of the intrinsic/extrinsic distinction in each case. Sider, in the course of defending the philosophical interest of the qualitative/non-qualitative distinction, makes a start on doing this. He notes that in the debates about supervenience, the distinction that is usually relevant is the qualitative/non-qualitative one. If we let *being (identical to) X* be an intrinsic property, then most of the supervenience theses discussed will be trivially true, because it will be impossible to have duplicates that are different objects, and hence impossible to have duplicates that differ with respect to the contents of their beliefs, or the justificatory status of their beliefs, or their phenomenal states, or whatever. But these theses are not trivially true; so if we are to formulate the distinctions this way, we had better not let identity properties be intrinsic *in these contexts*.

This, of course, does not show that the qualitative/non-qualitative distinction is the only one that can do philosophical work. Indeed, when trying to grasp what real change amounts to, it seems to be the interior/exterior distinction that is relevant. Say that *a* has *b* as a part, and consider the event whereby *b* is replaced in *a* by *c*, which happens to be a duplicate of *b*. This event seems to constitute a real change in *a*, not merely a Cambridge change, but it does not constitute a change in qualitative properties.

3. Attempts at Analysis

We will first look at two attempts to analyse the qualitative/non-qualitative distinction, and then at two more ambitious projects that aim to capture intrinsicness in all of its facets.

3.1 Combinatorial Theories

As Yablo noted, if an object has a property intrinsically, then it has it independently of the way the rest of the world is. The rest of the world could disappear, and the object might still have that property. Hence a *lonely* object, an object that has no wholly distinct worldmates, could have the property. Note that in the sense relevant here, two objects are only ‘wholly distinct’ if they have no parts in common, not if they are merely non-identical. The idea is that a lonely object could have proper parts. This is good, since *having six proper parts* is presumably an intrinsic property. Many extrinsic properties could not be possessed by lonely objects – no lonely object is six metres from a rhododendron, for example.

This suggests an analysis of intrinsicness: *F* is an intrinsic property iff it is possible for a lonely object to be *F*. This analysis is usually attributed to Kim (1982) (e.g. in Lewis 1983a and Sider 1993), though Humberstone (1996) dissents from this interpretation. Both directions of the biconditional can be challenged.

Some objects change in mass over time: this is presumably an intrinsic property of those objects. If necessitarian theories of laws are true (as endorsed by Ellis 2001 and Shoemaker 1984), then there could not be a world with just that object, as the conservation of matter would be violated. If any kind of combinatorial analysis of intrinsicness can work, we have to assume something like Hume’s dictum that there are no necessary connections between distinct existences. Indeed, all combinatorial theories of intrinsicness do assume this, and further that the range of what is possible can be taken as given in crafting a theory of intrinsicness. This might be thought problematic, since the best way to formally spell out Hume’s dictum itself appeals to the concept of intrinsicness (Lewis 1986a: 87-91).

The analysis is only viable as an analysis of the qualitative/non-qualitative distinction, since it rules that *being a duplicate of David Lewis* is an intrinsic property. This feature, too, is shared by all combinatorial theories of intrinsicness.

The major problem with this analysis is that the ‘if’ direction of the biconditional is clearly false. As Lewis (1983) pointed out, the property *being lonely* is had by some possible lonely objects, but it is not intrinsic.

Rae Langton and David Lewis (1998) designed a theory to meet this objection. Their theory resembles, in crucial respects, the theory sketched in an appendix to Dean Zimmerman’s paper "Immanent Causation" (Zimmerman 1997). The two theories were developed entirely independently. We will focus on Langton and Lewis’s version here, because it is more substantially developed, and more widely

discussed in the literature. On their theory, a property *F* is *independent of accompaniment* iff the following four conditions are met:

a. There exists a lonely *F*
b. There exists a lonely non-*F*
c. There exists an accompanied (i.e. not lonely) *F*
d. There exists an accompanied non-*F*

Langton and Lewis's idea is that if *F* is intrinsic, then whether *or not* an object is *F* should not depend on whether *or not* it is lonely. So all four of these cases should be possible. Still, some extrinsic properties satisfy all four conditions. Consider, for instance, the property *being lonely and round or accompanied and cubical*. A lonely sphere suffices for (a), a lonely cube for (b), an actual cube for (c) and an actual sphere for (d). So they have to rule out this property. They do it by the following five-step process.

First, Langton and Lewis identify a class of privileged *natural* (or non-disjunctive) properties. Lewis (1983b) had argued that we need to recognise a distinction between natural and non-natural properties to make sense of many debates in metaphysics, philosophy of science, philosophy of language and philosophy of mind, and suggested a few ways we might draw the distinction. We might take the natural properties to be those that correspond to real universals, or those that appear in the canonical formulations of best physics or regimented common sense, or even take the distinction to be primitive. Langton and Lewis say that it should not matter how we draw the distinction for present purposes, as long as we have it, and properties like *being lonely and round or accompanied and cubical* are not natural.

Secondly, they say properties are *disjunctive* iff they "can be expressed by a disjunction of (conjunctions of) natural properties; but are not themselves natural properties." Thirdly, they say a property is *basic intrinsic* iff it is non-disjunctive and satisfies (a) through (d). Fourthly, they say two (possible) objects are duplicates iff they share the same basic intrinsic properties. Finally, they say *F* is an intrinsic property iff two duplicates never differ with respect to it.

Three objections have been pressed against this view. Stephen Yablo (1999) objected to the role of natural properties in the analysis, which he argued introduced irrelevant material, and implied that the theory was at best *de facto*, but not *de jure*, correct. Dan Marshall and Josh Parsons (2001) claimed that according to this definition, the property *being such that a cube exists* is non-disjunctive, but it satisfies (a) through (d), so it would be basic intrinsic, despite being extrinsic. Theodore Sider (2001) claimed that the theory could not handle *maximal* properties: properties of objects that are not shared by their large proper parts. Sider claims that *being a rock* is such a property: large parts of rocks are not rocks. So *being a rock* is extrinsic, since a duplicate of a large part of a rock might be a rock if it is separated from the rest of the rock. But, argued Sider, on some interpretations of 'natural property' it is natural, and hence basic intrinsic.

Brian Weatherson's (2001) theory was designed to meet these three objections. In his theory,

combinatorial principles of possibility are not used to derive characteristics of individual intrinsic properties, as Kim and Langton and Lewis do, but characteristics of the whole set of intrinsic properties. He argues that this set, call it *SI*, will have the following properties:

- If $F \in SI$ and $G \in SI$, then *F and G* $\in SI$ and *F or G* $\in SI$ and *not F* $\in SI$
- If $F \in SI$ then *Having* n *parts that are F* $\in SI$ and *Being entirely composed of exactly* n *things that are F* $\in SI$
- If $F \in SI$ and $G \in SI$ and there is a possible world with n+1 pairwise distinct things, and something in some world is *F* and something in some world is *G*, then there is a world with exactly n+1 pairwise distinct things such that one is *F* and the other n are *G*.
- If $F \in SI$ and $G \in SI$ and it is possible that regions with shapes d_1 and d_2 stand in relation *A*, and it is possible that an *F* wholly occupy a region with shape d_1 and a *G* wholly occupy a region with shape d_2, then there is a world where regions with shapes d_1 and d_2 stand in *A*, and an *F* wholly occupies the region with shape d_1 and a *G* wholly occupies the region with shape d_2.

The first two principles are closure principles on the set. The third principle says that any two intrinsic properties that can be instantiated can be instantiated together any number of times. And the fourth says that if objects having two intrinsic properties can be in two regions, and those two regions can be in a particular spatial relation, then the regions can be in that relation while filled by objects having those properties. The third principle suffices to show that *being such that a cube exists* could not be in *SI*, and the fourth to show that *being a rock* could not be.

Weatherson's theory does not entirely avoid appeals to a concept of naturalness, though the counterexamples that prompt the appeal are now much more recherché. Without such an appeal, then if *F* and *G* are intrinsic properties that atoms could have, nothing in his theory rules out the property *being simple, lonely and F or being G* from being intrinsic. There are a few ways for the appeal to go at this point, see Weatherson (2001) and Lewis (2001) for a few suggestions. The following moves, taken directly from Langton and Lewis, will probably work if any will. Say that the basic intrinsic properties are those non-disjunctive properties such that their membership in *SI* is consistent with the above four principles. Two objects are duplicates if they do not differ with respect to basic intrinsic properties. A property is intrinsic if it never differs between duplicates.

Finally, John Hawthorne (2001) has suggested that all these combinatorial theories have a problem with properties of the form *being R-related to something*, where *R* is a perfectly natural relation that is neither reflexive nor irreflexive. Such properties are extrinsic, but Hawthorne suggests they will satisfy all the combinatorial principles, and their close connection to natural relations means that they will be natural enough to cause problems for all these combinatorial approaches.

3.2 Natural Kind Theories

In *On the Plurality of Worlds*, David Lewis presents a quite different analysis of intrinsic properties. As

with the combinatorial theory that he and Rae Langton defend, it heavily exploits the idea that some properties are more natural than others. In fact, it rests even more weight on it. Here is Lewis's statement of the theory:

> [I]t can plausibly be said that all perfectly natural properties are intrinsic. Then we can say that two things are *duplicates* iff (1) they have exactly the same perfectly natural properties, and (2) their parts can be put into correspondence in such a way that corresponding parts have exactly the same perfectly natural properties, and stand in the same perfectly natural relations…Then we can go on to say that an *intrinsic* property is one that can never differ between duplicates. (Lewis 1986a: 61-2)

Like the combinatorial theories, this is an attempt at analysing qualitative intrinsicness. Anyone who thinks this is too modest an aim to be worthwhile will be disappointed. It rests heavily on the 'plausible' claim that all perfectly natural properties are intrinsic, and, implicitly, that the perfectly natural properties are sufficient to characterise the world completely. The last assumption is needed because the theory rules out the possibility that there are two objects that share all their perfectly natural properties, but differ with respect to some intrinsic property or other. One consequence of these assumptions is that a world is fully characterised by the intrinsic properties of its inhabitants and the perfectly natural relations between those inhabitants. Lewis thinks this is true for the actual world, it is just his doctrine of Humean supervenience. (Lewis 1986b: i-xiii). But it might be thought a stretch to think it is true of *all* worlds.

In their paper of 1998, Langton and Lewis claim the only advantage of their theory over Lewis's old theory is that it makes fewer assumptions about the nature of natural properties. They also note that Lewis still believes those assumptions, but they think it is worthwhile to have a theory that gets by without them. It also seems that Lewis's new theory, perhaps as amended, provides more insight into the nature of intrinsicness.

3.3 Contractions

Peter Vallentyne (1997) develops a theory based around the idea that *x*'s intrinsic properties are those properties it would have if it were alone in the world. He defines a *contraction* of a world as "a world 'obtainable' from the original one solely by 'removing' objects from it." (211) As a special case of this, an *x*-*t* contraction, where *x* is an object and *t* a time, is "a world 'obtainable' from the original one by, to the greatest extent possible, 'removing' all objects wholly distinct from *x*, all spatial locations not occupied by *x*, and all times (temporal states of the world) except *t*, from the world." (211) Vallentyne allows that there might be unique *x*-*t* contraction; sometimes we can remove one of two objects, but not both, from the world while leaving *x*, so there will be one *x*-*t* contraction which has one of these in it, and another that has the other.

He then says that *F* is intrinsic iff for all *x*, *t*, all *x*-*t* contractions are such that *Fx* is true in the contraction iff it is true in the actual world. In short, a property is intrinsic to an object iff removing the rest of the world doesn't change whether the object has the property.

Vallentyne notes that this definition will not be very enlightening unless we understand the idea of a contraction. This seems related to the objection Langton and Lewis (1998) urge against Vallentyne. They say that Vallentyne's account reduces to the claim that a property is intrinsic iff possession of it never differs between an object and its lonely duplicates, a claim they think is true but too trivial to count as an analysis. Their position is that we cannot understand contractions without understanding duplication, but if we understand duplication then intrinsicness can be easily defined, so Vallentyne's theory is no advance.

Stephen Yablo (1999) argues that this criticism is too quick. Vallentyne should best be understood as working within a very different metaphysical framework to Lewis. For Lewis, no (ordinary) object exists at more than one world, so Vallentyne's contractions, being separate worlds, must contain separate objects. Hence *x-t* contractions can be nothing other than lonely duplicates, and the theory is trivial. Yablo suggests that the theory becomes substantive relative to a metaphysical background in which the very same object can appear in different worlds. (In chapter 4 of *Plurality* Lewis has a few arguments against this idea, and Yablo has interesting responses to these arguments. A thorough investigation of this debate would take us too far from the topic.) If this is the case then we can get a grip on contractions without thinking about duplications - the *x-t* contraction of a world is the world that contains *x* itself, and as few other things as possible.

3.4 Francescotti

Robert Franscecotti (1999) recently outlined an analysis that takes the concept of intrinsicness as non-relationality to be primary. Francescotti takes a property to be extrinsic iff an object possesses it in virtue of its relations to other objects. So *being a duplicate of Jack* and *being such that the number 17 exists* are extrinsic, while *being identical to Jack* and *being a vertebrate* (i.e. *having a vertebral column*) are intrinsic. As noted above, this means that we must either have a hyper-intensional notion of properties, or we say that intrinsicness is a property of concepts, not of properties. Francescotti takes the former option.

Francescotti notes that not all relational properties are extrinsic. *Having a vertebral column*, for instance, seems to be relational in that it consists of a relation to a vertebral column, but it is also an intrinsic property. So he focuses on relations to distinct objects. The definition of intrinsicness goes as follows. First we define a d-relational property. *F* is d-relational iff:

> (a) there is a relation *R*, and an item *y*, such that (i) *x*'s having *F* consists in *x*'s bearing *R* to *y*, and (ii) *y is distinct from x*; or
>
> (b) there is a relation *R*, and a class of items *C*, such that (i) *x*'s having *F* consists in there being some member of *C* to which *x* bears *R*, and (ii) at least one member of *C* to which *x* bears *R* is distinct from *x*; or
>
> (c) there is a relation *R*, and a class of items *C*, such that (i) *x*'s having *F* consists in *x*'s

bearing *R* to every member of *C*, and (ii) it is possible that there is a member of *C* that is distinct from *x*.

We then define intrinsic properties as being those that are not d-relational.

F is an intrinsic property of $x =_{df} x$ has *F*, and *F* is not a d-relational property of *x*.

Francescotti's theory provides intuitively plausible answers to all the cases he considers, provided of course that we identify the intrinsic/non-intrinsic distinction with the relational/non-relational distinction, rather than one of the other two distinctions considered in section two. Like the other three theories, it has one unexplained (or perhaps underexplained) primitive, in this case the *consists-in* relation. As Francescotti notes, following Khamara (1988), it won't do to say *x*'s having *F* consists in *x*'s bearing *R* to *y* just in case it is necessary that *Fx* iff *xRy*. That makes it too easy for having a property to consist in some necessary being (say God, or the numbers) being a certain way. Rather, he says, "*x*'s having *F*, consists in the event or state, *x*'s having *G*, just in case *x*'s having *F* is the very same event or state as *x*'s having *G*." (599) Whether this can handle all the hard cases seems to depend how the theory of identity conditions for events and states turns out. (See the entries on Donald Davidson and events for some start on this.)

Thermodynamic Asymmetry in Time

Macroscopic processes appear to be temporally "directed" in some sense. The spontaneous evolution of systems is always to a future but not past equilibrium state. The nature of this directedness concerns many deep questions at the foundations of philosophy and science.

Thermodynamics is the science that describes much of the time-asymmetric behavior found in the world. This entry's first task, consequently, is to show how thermodynamics treats temporally 'directed' behavior. It then concentrates on the following two questions. (1) What is the origin of the thermodynamic asymmetry in time? In a world possibly governed by time-symmetric laws, how should we understand the time-asymmetric laws of thermodynamics? (2) Does the thermodynamic time asymmetry explain the other temporal asymmetries? Does it account, for instance, for the fact that we know more about the past than the future? The discussion thus divides between thermodynamics being an explanandum or explanans. In the former case the answer will concern philosophy of physics; in the latter case it will concern metaphysics, epistemology, and other fields, though in each case there will be blurring between the disciplines.

1. Thermodynamic Time Asymmetry: A Brief Guide

Consider the following.

> Place some chlorine gas in a small closed flask into the corner of a room. Set it up so that an automaton will remove its cover in 1 minute. Now we know what to do: run. Chlorine is poison, and furthermore, we know the gas will spread reasonably quickly through its available volume. The chlorine originally in equilibrium in the flask will, upon being freed,

> 'relax' to a new equilibrium.

Or less dramatically:

> Place an iron bar over a flame for half an hour. Place another one in a freezer for the same duration. Remove them and place them against one another. Within a short time the hot one will 'lose its heat' to the cold one. The new combined two-bar system will settle to a new equilibrium, one intermediate between the cold and hot bar's original temperatures. Eventually the bars will together settle to roughly room temperature.

These are two examples of a tendency of systems to spontaneously evolve to equilibrium; but there are indefinitely more examples in all manner of substance. The physics first used to describe such processes is thermodynamics.

First systematically developed in S. Carnot's *Reflections on the Motive Power of Fire* 1824, the science of classical thermodynamics is intimately associated with the industrial revolution. Most of the results responsible for the science originated from the practice of engineers trying to improve steam engines. Begun in France and England in the late eighteeth and early nineteenth centuries, the science quickly spread throughout Europe. By the mid-nineteenth century, Clausius in Germany and Thompson in England had developed the theory in great detail.

Thermodynamics is a 'phenomenal' science, in the sense that the variables of the science range over macroscopic parameters such as temperature and volume. Whether the microphysics underlying these variables are motive atoms in the void or an imponderable fluid is largely irrelevant to this science. The developers of the theory both prided themselves on this fact and at the same time worried about it. Clausius, for instance, was one of the first to speculate that heat consisted solely of the motion of particles (without an ether), for it made the equivalence of heat with mechanical work less surprising. However, as was common, he kept his ontological beliefs separate from his statement of the principles of thermodynamics because he didn't wish to (in his words) "taint" the latter with the speculative character of the former.[1.]

A treatment of thermodynamics naturally begins with the statements it takes to be laws of nature. These laws are founded upon observations of relationships between particular macroscopic parameters and they are justified by the fact they are empirically adequate. No further justification of these laws is to be found -- at this stage -- from the details of microphysics. Rather, stable, counterfactual-supporting generalizations about macroscopic features are enshrined as law. The typical textbook treatment of thermodynamics describes some basic concepts, states the laws in a more or less rough way and then proceeds to derive the concepts of temperature and entropy and the various thermodynamic equations of state. It is worth remarking, however, that in the last forty years the subject has been presented with a degree of mathematical rigor not previously achieved. Originating from the early axiomatization by Caratheodory in 1909, the development of 'rational thermodynamics' has clarified the concepts and logic of classical thermodynamics to a degree not generally appreciated. There now exist many quite different,

mathematically exact approaches to thermodynamics, each starting with different observational regularities as axioms. (For a popular presentation of a recent axiomatization, see Lieb and Yngvson 2000.)

In the traditional approach classical thermodynamics has two laws, the second of which is our main focus. (Readers may have heard of a ’third law’ as well, but it was added later and is not relevant to the present discussion.) The first law expresses the conservation of energy. The law uses the concept of the internal energy of a system, $U(x)$, which is a function of variables such as volume. For thermally isolated (adiabatic) systems--think of systems such as coffee in a thermos--the law states that this function, $U(x)$, is such that the work W delivered to a system’s surroundings is compensated by a loss of internal energy, i.e., $dW = -dU$. When Joule and others showed that mechanical work and heat were interconvertible, consistency with the principle of energy conservation demanded that heat, Q, considered as a different form of energy, be taken into account. For non-isolated systems we extend the law as $dQ = dU + dW$, where dQ is the differential of the amount of heat added to the system (in a reversible manner).

The conservation of energy tells us nothing about temporally asymmetric behavior. In particular, it doesn’t follow from the first law that interacting systems quickly tend to approach equilibrium (a state where the values of the macroscopic variables remain approximately stable), and once achieved, never leave this state. It is perfectly consistent with the first law that systems in equilibrium leave equilibrium. Since this tendency of systems cannot be derived from the First Law, another law is needed. Although S. Carnot was the first to state it, the formulations of Kelvin and Clausius are standard:

> Kelvin’s Second Law: There is no thermodynamic process whose sole effect is to transform heat extracted from a source at uniform temperature completely into work.
>
> Clausius’ Second Law: There is no thermodynamic process whose sole effect is to extract a quantity of heat from a colder reservoir and deliver it to a hotter reservoir.

Kelvin’s version is essentially the same as the version arrived at by both Carnot and Planck, whereas Clausius’ version differs from these in a few ways.[2.]

Clausius’ version transparently rules out anti-thermodynamic behavior such as a hot iron bar extracting heat from a neighboring cold iron bar. The cool bar cannot give up a quantity of heat to the warmer bar (without something else happening). Kelvin’s statement is perhaps less obvious. It stems from the fact familiar from steam engines that heat energy is a ‘poor’ grade of energy. Consider a gas-filled cylinder with a frictionless piston holding the gas down at one end. If we put a flame under the cylinder, the gas will expand and the piston can perform work, e.g., it might move a ball. However, we can never convert the heat energy straight into work without some other effect occurring. In this case, the gas occupies a larger volume.

In 1865 Clausius introduced the notion of the ‘equivalence value’ of a system, a concept that is the ancestor of the modern day concept of entropy. Later in 1865 Clausius used the term ‘entropy’ from the

Greek word for transformation. The entropy of a state *A*, *S*(*A*), for instance, is defined as the integral $S(A) = \int_O^A dQ/T$ over a reversible transformation, where *O* is some arbitrary fixed state. For *A* to have an entropy, the transformation from *O* to *A* must be quasi-static, i.e., a succession of equilibrium states. Continuity considerations then imply that the initial and final states *O* and *A* must also be equilibrium states.

In terms of entropy, the Second Law states that in a transformation from equilibrium state *A* to equilibrium state *B*, the inequality *S*(*B*) - *S*(*A*) is greater than or equal to the $\int_B^A dQ/T$. Loosely put, for realistic systems, this implies that in the spontaneous evolution of a thermally closed system the entropy can never decrease and that it attains its maximum value for states at equilibrium. We are invited to think of the Second Law as driving the gas to its new, higher entropy equilibrium state. Using this concept of entropy, thermodynamics is able to capture an extraordinary range of phenomena under one simple law. Remarkably, whether they are gases filling their available volumes, two iron bars in contact coming to the same temperature, or milk mixing in your coffee, they all have an observable property in common: their entropy increases. Coupled with the First Law, the Second Law is remarkably powerful. It appears that all classical thermodynamical behavior can be derived from these two simple statements (Penrose 1970).[3.]

There are a number of philosophical questions one might ask about the the laws of thermodynamics. For instance, where exactly is time-asymmetry found in the above statement of the Second Law? Why think the Second Law is universal? (See Uffink 2001 for an interesting discussion of these topics.) How are these laws framed in a relativistic universe? Do Lorentz boosted gases appear hotter or colder in the new frame? Surprisingly, the correct (special) relativistic transformation rules for thermodynamic quantities, and thus the relativistic understanding of thermodynamic time asymmetry, is still controversial. With all the current activity of physicists being focused on the thermodynamics of black holes in general relativity and quantum gravity, it is amusing to note that special relativistic thermodynamics is still a field with many open questions, both physically and philosophically. (See Earman 1981 and Liu 1994.)

Another important question concerns the reduction of thermodynamic concepts such as entropy to their mechanical, or statistical mechanical, basis. As even a cursory glance at statistical mechanics reveals, there are many candidates for the statistical mechanical entropy, each the center of a different program in the foundations of the field. Here, again, surprisingly, there is no consensus as to which entropy is best suited to be the reduction basis of the thermodynamic entropy (see Sklar 1993; Callender 1999). Consequently, there is little agreement about what the Second Law looks like in statistical mechanics. Despite the worthiness of these issues, this article will focus on the particularly important problem of the direction of time (though as we'll see, many issues go by this name.)

2. The Problem of the Direction of Time I

This 'problem of the direction of time' has its source in the debates over the status of the second law of

thermodynamics between L. Boltzmann and some of his contemporaries, notably, J. Loschmidt, E. Zermelo and E. Culverwell. Boltzmann sought the mechanical underpinning of the second law. He came up with a particularly ingenious explanation for why systems tend toward equilibrium. Consider an isolated gas of N particles in a box, where N is large enough to make the system macroscopic ($N \approx 10^{23}+$). For the sake of familiarity we will work with classical mechanics. We can characterize the gas by the coordinates and momenta x_{in}, p_{in} of each of its particles and represent the whole system by a point $X = (q,p)$ in a $6N$-dimensional phase space known as Γ, where $q = (q_1 \ldots q_{3N})$ and $p = (p_1 \ldots p_{3N})$.

Boltzmann's great insight was to see that the thermodynamic entropy arguably "reduced" to the volume in Γ picked out by the macroscopic parameters of the system. The key ingredient is partitioning Γ into compartments, such that all of the microstates X in a compartment are macroscopically (and thus thermodynamically) indistinguishable. To each macrostate M, there corresponds a volume of Γ, $|\Gamma_M|$, whose size will depend on the macrostate in question. For combinatorial reasons, almost all of Γ corresponds to a state of thermal equilibrium. There are simply many more ways to be distributed with uniform temperature and pressure than ways to be distributed with nonuniform temperature and pressure. There is a vast numerical imbalance in Γ between the states in thermal equilibrium and the states in thermal nonequilibrium.

We can now introduce Boltzmann's famous entropy formula (up to an additive constant):

$$S_B(M(X)) = k \log |\Gamma_M|$$

where $|\Gamma_M|$ is the volume in Γ associated with the macrostate M, and k is Boltzmann's constant. S_B provides a relative measure of the amount of Γ corresponding to each M. Given the mentioned asymmetry in Γ, almost all microstates are such that their entropy value is overwhelmingly likely to increase with time. When the constraints are released on systems initially confined to small sections of Γ, typical systems will evolve into larger compartments. Since the new equilibrium distribution occupies *almost all* of the newly available phase space, nearly all of the microstates originating in the smaller volume will tend toward equilibrium. Except for those incredibly rare microstates conspiring to stay in small compartments, microstates will evolve in such a way as to have S_B increase. Though substantial questions can be raised about the details of this approach, and philosophers can rightly worry about the justification of the standard probability measure on Γ, this explanation seems to offer the correct *framework* for understanding why the entropy of systems tends to increase with time. (For further explanation and discussion see Bricmont 1996, Callender 1999, Goldstein 2001, Klein 1973 and Lebowitz 1993.)

Before Boltzmann described entropy increase as described above, he proposed a now notorious "proof" known as the "H-theorem" to the effect that entropy must always increase. Loschmidt and Zermelo launched objections to the H-theorem. But an objection in their spirit can also be advanced against Boltzmann's later view sketched above. Loosely put, because the classical equations of motion are time reversal invariant (TRI), nothing in the original explanation necessarily referred to the direction of time.

(See Hurley 1985.) Though I just stated the Boltzmannian account of entropy increase in terms of entropy increasing into the future, the explanation can be turned around and made for the past temporal direction as well. Given a gas in a box that is in a nonequilibrium state, the vast majority of microstates that are *antecedents* of the dynamical evolution leading to the present macrostate correspond to a macrostate with *higher entropy* than the present one. Therefore, not only is it highly likely that typical microstates corresponding to a nonequilibrium state will evolve to higher entropy states, but it is also highly likely that they *evolved from* higher entropy states.

Concisely put, the problem is that given a nonequilibrium state at time t_2, it is overwhelmingly likely that

> (1) the nonequilibrium state at t_2 will evolve to one closer to equilibrium at t_3

but that due to the reversibility of the dynamics it is also overwhelmingly likely that

> (2) the nonequilibrium state at t_2 has evolved from one closer to equilibrium at t_1

where $t_1 < t_2 < t_3$. However, transitions described by (2) do not seem to occur; or phrased more carefully, not both (1) and (2) occur. However we choose to use the terms ‘earlier’ and ‘later,’ clearly entropy doesn’t increase in both temporal directions. For ease of exposition let us dub (2) the culprit.

The traditional problem is not merely that nomologically possible (anti-thermodynamic) behavior does not occur when it could. That is not straightforwardly a problem: *all sorts* of nomologically allowed processes do not occur. Rather, the problem is that statistical mechanics seems to make a prediction that is falsified, and that is a problem according to anyone’s theory of confirmation.

Many solutions to this problem have been proposed. Generally speaking, there are two ways to solve the problem: eliminate transitions of type (2) either with special boundary conditions or with laws of nature. The former method works if we assume that *earlier* states of the universe are of comparatively low-entropy *and* that (relatively) *later* states are not also low-entropy states. There are no high-to-low-entropy processes simply because earlier entropy was very low. Alternatively, the latter method works if we can somehow restrict the domain of physically possible worlds to those admitting only low-to-high transitions. The laws of nature are the straightjacket on what we deem physically possible. Since we need to eliminate transitions of type (2) while keeping those of type (1) (or vice versa), a necessary condition of the laws doing this job is that they be time reversal noninvariant. Our choice of strategy boils down to either assuming temporally asymmetric boundary conditions or of adding (or changing to) time reversal noninvariant laws of nature. Many approaches to this problem have thought to avoid this dilemma, but a little analysis of any proposed ‘third way’ arguably proves this to be false.

2.1 Past Hypothesis

Without changing the TRI laws of nature, there is no way to eliminate transition (2) in favor of (1).

Nevertheless, appealing to temporally asymmetric boundary conditions, as we've seen, allow us to describe a world wherein (1) but not (2) occur. A cosmological hypothesis claiming that in the very distant past entropy was much lower will work. Boltzmann, as well as many of this century's greatest scientists, e.g., Einstein, Feynman, and Schroedinger, saw that this hypothesis is necessary given our laws. (Boltzmann, however, explained this low-entropy condition by treating the observable universe as a natural statistical fluctuation away from equilibrium in a vastly larger universe.) Earlier states do not have higher entropy than present states because we make the cosmological posit that the universe began in an extremely tiny section of its available phase space. Albert 2000 calls this the "Past Hypothesis" and provides a detailed discussion of its role in statistical mechanics.

Classical mechanics is also compatiable with a "Future Hypothesis": the claim that entropy is very low in the distant future. The restriction to "distant" is needed, for if the near future were of low-entropy, we would not expect the thermodynamic behavior that we see -- see Cocke 1967, Price 1996 and Schulman 1997 for discussion of two-time boundary conditions.

The main dissatisfaction with this solution is that many do not find it sufficiently *explanatory* of thermodynamic behavior. That a gas in the lab last Wednesday filled its available volume due to special initial conditions may be credible. But that gases everywhere for all time should expand through their available volumes due to special initial conditions is, for some, incredible. The common cause of these events is viewed as unlikely. Expressing this feeling, Penrose 1989 estimates that the probability, given the standard measure on phase space, of the universe starting in the requisite state is astronomically small. Callender 1997, however, assimilates the problem to the general one facing the special sciences -- all special science laws require conspiratorial initial conditions for their generalizations to hold. If the problem really is a problem, according to Callender, it is not necessarily one specific to thermodynamics and time's direction.

2.2 Electromagnetism

The physicist E. Ritz and others have claimed that electromagnetism accounts for the thermodynamic arrow. The wave equation for both mechanical and electromagnetic processes is well-known to include both 'advanced' and 'retarded' solutions. The retarded solution

$$\phi_{\text{ret}}(r,t) = \int dr' \rho \frac{(r', t - \frac{|r'-r|}{c})}{|r'-r|}$$

gives the field amplitude φ_{ret} at *r,t* by finding the source density *r* at r' at earlier times. The advanced solution

$$\phi_{\mathrm{adv}}(r,t) = \int dr' \rho \frac{(r', t + \frac{|r'-r|}{c})}{|r'-r|}$$

gives the field amplitude in terms of the source density at r' at later times. Despite this symmetry nature seems to contain only processes obeying the retarded solutions. (This popular way of stating the electromagnetic asymmetry is actually misleading. The advanced solutions describe the radiation sink's receiving waves, and this happens all the time. The asymmetry of radiation instead lay with the form (concentrated or dispersed) the sources take.)

If we place an isolated concentrated gas in the middle of a large volume, we would expect the particles to spread out in an expanding sphere about the center of the gas, much as radiation spreads out. It is therefore tempting to think that there is a relationship between the thermodynamic and electromagnetic arrows of time. In a debate in 1909, A. Einstein and E. Ritz disagreed about the nature of this relationship. Ritz took the position that the asymmetry of radiation had to be judged lawlike and that the thermodynamic asymmetry could be derived from this law. Einstein's position is instead that "irreversibility is exclusively based on reasons of probability" (Einstein and Ritz 1909, quoted from Zeh 1989, 13). It is unclear whether he meant probability plus the right boundary conditions, or simply probability alone. In any case, Ritz believes the radiation arrow causes the thermodynamic one, whereas Einstein seems to hold something closer to the opposite position.

It seems that Einstein must be right, or at least, closer to being correct than Ritz. Ritz' position appears implausible if only because it implies gases composed of neutral particles will not tend to spread out. That aside, we now think that the wave asymmetry must originate in asymmetric boundary conditions, just as the statistical mechanical asymmetry may. Recall the statistical version of the Second Law. It implies that with the right (improbable) initial conditions a system will undergo improbable-to-probable transitions rather than the reverse. The crucial point to see is that the usual retarded radiation is a kind of improbable-to-probable transition. A concentrated source is improbable, but given its existence, a system will evolve toward more probable regions of the phase space, i.e., the waves will spread. Advanced radiation is likewise a species of improbable-to-probable transitions. Given an improbable source in the past, it will spread backwards in time to more probable regions of the phase space too. Using Popper's famous mechanical wave example as an analogy, throwing a rock into a pond so that waves on the surface spread out into the future requires every bit the conspiracy that is needed for waves to converge on a point in order to eject a rock from the bottom. Both are equally likely, pace Popper; whether one or both happen depends upon the boundary conditions. The real asymmetry lies in the fact that in the past there are concentrated sources for waves, whereas in the future there tend not to be. See Price 1996, Arntzenius 1993, and Frisch 2000 for discussion of this controversial point.

These considerations do not mean the radiation arrow *reduces* in any sense to the thermodynamic arrow. Rather, the thing to say is that the radiation arrow just seems to *be* the statistical mechanical one, with the qualification that the media sustaining the improbable-to-probable transition is electromagnetic.

2.3 Cosmology

Cosmology presents us with a number of apparently temporally asymmetric mechanisms. The most obvious one is the inexorable expansion of the universe. In cosmology the spatial scale factor $a(t)$, which gives the distance between co-moving observers, is increasing. The universe seems to be uniformly expanding relative to our local frame. Since this temporal asymmetry occupies a rather unique status it is natural to wonder whether it might be the 'master' arrow. The cosmologist T. Gold 1962 proposed just this. Believing that entropy values covary with the size of the universe, Gold asserts that at the maximum radius the thermodynamic arrow will 'flip' due to the re-contraction. However, as Tolman 1936 has shown in some detail, a universe filled with non-relativistic particles will not suffer entropy increase due to expansion, nor will an expanding universe uniformly filled with blackbody radiation increase its entropy either. Interestingly, Tolman demonstrated that more realistic universes containing both matter and radiation *will* change their entropy contents. Coupled with expansion, various processes will contribute to entropy increase, e.g., energy will flow from the 'hot' radiation to the 'cool' matter. So long as the relaxation time of these processes is larger than the expansion time scale, they should generate entropy. We thus have a purely cosmological method of entropy generation.

Others (e.g., Davies 1994) have thought inflation provides a kind of entropy-increasing behavior -- again, given the sort of matter content we have in our universe. The inflationary model is an alternative of sorts to the standard big bang model, although by now it is so well entrenched in the cosmology community that it really deserves the tag 'standard'. In this scenario, the universe is very early in a quantum state called a 'false vacuum', a state with a very high energy density and negative pressure. Gravity acts like Einstein's cosmological constant, so that it is repulsive rather than attractive. Under this force the universe enters a period of exponential inflation, with geometry resembling de Sitter space. When this period ends any initial in-homogeneities will have been smoothed to insignificance. At this point ordinary stellar evolution begins. Loosely associating gravitational homogeneity with low-entropy and inhomogeneity with higher entropy, inflation is arguably another source of cosmological entropy generation.

There are other proposed sources of cosmological entropy generation, but these should suffice to give the reader a flavor of the idea. We shall not be concerned with evaluating these scenarios in any detail. Rather, our concern is about how these proposals explain time's arrow. In particular, how do they square with our earlier claim that the issue boils down to either assuming temporally asymmetric boundary conditions or of adding time reversal non-invariant laws of nature?

The answer is not always clear, owing in part to the fact that the separation between laws of nature and boundary conditions is especially slippery in the science of cosmology. Advocates of the cosmological explanation of time's arrow typically see themselves as explaining the origin of the needed low-entropy cosmological condition. Some explicitly state that special initial conditions are needed for the thermodynamic arrow, but differ with the conventional 'statistical' school in deducing the origin of these initial conditions. Earlier low-entropy conditions are not viewed as the boundary conditions of the spacetime. They came about, according to the cosmological schools, about a second or more after the big

bang. But when the universe is the size of a small particle, a second or more is enough time for some kind of cosmological mechanism to bring about our low-entropy 'initial' condition. What cosmologists (primarily) differ about is the precise nature of this mechanism. Once the mechanism creates the 'initial' low-entropy we have the same sort of explanation of the thermodynamic asymmetry as discussed in the previous section. Because the proposed mechanisms are supposed to make the special initial conditions inevitable or at least highly probable, this maneuver seems like the alleged 'third way' mentioned above.

The central question about this type of explanation, as far as we're concerned, is this: Is the existence of the low 'initial' state a consequence of the laws of nature alone or the laws plus boundary conditions? In other words, first, does the proposed mechanism produce low-entropy states given *any* initial condition, and second, is it a *consequence* of the laws *alone* or a consequence of the laws *plus initial conditions*? We want to know whether our question has merely been shifted back a step, whether the explanation is a disguised appeal to special initial conditions. Though we cannot here answer the question in general, we can say that the two mechanisms mentioned are not lawlike in nature. Expansion fails on two counts. There are boundary conditions in expanding universes that do not lead to an entropy gradient, i.e., conditions without the right matter-radiation content, and there are boundary conditions that do not lead to expansion, e.g., matter-filled Friedman models that do not expand. Inflation fails at least on the second count. Despite advertising, arbitrary initial conditions will not give rise to an inflationary period (Earman 1995, pp. 152-3). Furthermore, it's not clear that inflationary periods will give rise to thermodynamic asymmetries (Price 1996, ch. 2). The cosmological scenarios do not seem to make the thermodynamic asymmetries a result of nomic necessity. The cosmological hypotheses may be true, and in some sense, they may even explain the low-entropy initial state. But they do not appear to provide an explanation of the thermodynamic asymmetry that makes it nomologically necessary or even likely.

Another way to see the point is to consider the question of whether the thermodynamic arrow would 'flip' if (say) the universe started to contract. Gold, as we said above, asserts that at the maximum radius the thermodynamic arrow must 'flip' due to the re-contraction. Not positing a thermodynamic flip while maintaining that entropy values covary with the radius of the universe is clearly inconsistent -- it is what Price 1996 calls the fallacy of a "temporal double standard". Gold does not committ this fallacy, and so he claims that the entropy must decrease if ever the universe started to re-contract. However, as Albert 2000 writes, "there are plainly locations in the phase space of the world from which ... the world's radius will inexorably head up and the world's entropy will exorably head down". Since that it is the case, it doesn't follow from law that the thermodynamic arrow will flip during re-contraction; therefore, without changing the fundamental laws, the Gold mechanism cannot explain the thermodynamic arrow in the sense we want.

From these considerations we can understand what Price 1996 calls the *basic dilemma*: either we explain the earlier low-entropy condition Gold-style or it is inexplicable by time-symmetric physics (82). Because there is no net asymmetry in a Gold universe, we might paraphrase Price's conclusion in a more disturbing manner as the claim that the (local) thermodynamic arrow is explicable just in case (globally) there isn't one. However, notice that this remark leaves open the idea that the laws governing expansion or inflation are not TRI. (For more on Price's basic dilemma, see Callender 1998 and Price 1995.)

2.4 Quantum Cosmology

Quantum cosmology, it is often said, is the *theory* of the universe's initial conditions. Presumably this entails that its posits are to be regarded as lawlike. Because theories are typically understood as containing a set of laws, quantum cosmologists apparently assume that the distinction between laws and initial conditions is fluid. Particular initial conditions will be said to obtain as a matter of law. Hawking 1987 writes, for example, "we shall not have a complete model of the universe until we can say more about the boundary conditions than that they must be whatever would produce what we observe," (163). Combining such aspirations with the observation that thermodynamics requires special boundary conditions leads quite naturally to the thought that “the second law becomes a selection principle for the boundary conditions of the universe [for quantum cosmology]” (Laflamme 1994, 358). In other words, if one is to have a theory of initial conditions, it would certainly be desirable to deduce initial conditions that will lead to the thermodynamic arrow. This is precisely what many quantum cosmologists have sought.[5.] Since quantum cosmology is currently very speculative, it has been argued that it is premature to start worrying about what it says about time's arrow (Callender 1998). Nevertheless, there has been a substantial amount of debate on this issue (see Haliwell *et al*, 1994).

2.5 Time Itself

Some philosophers have sought an answer to the problem of time's arrow by claiming that time *itself* is directed. They do not mean time is asymmetric in the sense intended by advocates of the tensed theory of time. Their proposals are firmly rooted in the idea that time and space are properly represented on a four-dimensional manifold. The main idea is that the asymmetries in time indicate something about the nature of time itself. Christensen 1993 argues that this is the most economical response to our problem since it posits nothing besides time as the common cause of the asymmetries, and we already believe in time. A proposal similar to Christensen's is Weingard's 1977 ‘time-ordering field’. Weingard's speculative thesis is that spacetime is temporally oriented by a ‘time potential,’ a timelike vector field that at every spacetime point directs a vector into its future light cone. In other words, supposing our spacetime is temporally orientable, Weingard wants to actually orient it. The main virtue of this is that it provides a time sense everywhere, even in spacetimes containing closed timelike curves (so long as they're temporally orientable). As he shows, any explication of the ‘earlier than’ relation in terms of some other physical relation will have trouble providing a consistent description of time direction in such spacetimes. Another virtue of the idea is that it is in principle capable of explaining *all* the temporal asymmetries. If coupled to the various asymmetries in time, it would be the ‘master arrow’ responsible for the arrows of interest. As Sklar 1985 notes, Weingard's proposal makes the past-future asymmetry very much like the up-down asymmetry. As the up-down asymmetry was reduced to the existence of a gravitational potential -- and not an asymmetry of space itself -- so the past-future asymmetry would reduce to the time potential -- and not an asymmetry of time itself. Of course, if one thinks of the gravitional metric field as part of spacetime, there is a sense in which the reduction of the up-down asymmetry really was a reduction to a spacetime asymmetry. And if the metric field is conceived as part of spacetime -- which is itself a huge source of contention in philosophy of physics -- it is natural to think of Weingard's time-ordering field as also part of spacetime. Thus his proposal shares a lot in common

with Christensen's suggestion.

This sort of proposal has been criticized by both Earman and Sklar on methodological grounds. Sklar 1985, for instance, claims that scientists would not accept such an explanation (111-2). One might point out, however, that many scientists did believe in analogues of the time-ordering field as possible causes of the CP violations.[6.] The time-ordering field, if it exists, would be an unseen (except through its effects) common cause of strikingly ubiquitous phenomena. Scientists routinely accept such explanations. To find a problem with the time-ordering field we need not invoke methodological scruples; instead we can simply ask whether it does the job asked of it. Is there a mechanism that will couple the time-ordering field to thermodynamic phenomena? Weingard says the time potential field needs to be suitably coupled (p. 130) to the non-accidental asymmetric processes, but neither he nor Christensen elaborate on how this is to be accomplished. Until this is addressed satisfactorily, this speculative idea must be considered interesting yet embryonic.

2.6 Interventionism

When explaining time's arrow, many philosophers and physicists have focused their attention upon the unimpeachable fact that real systems are open systems that are subjected to interactions of various sorts.[7.] We can not truly isolate thermodynamic systems, and even if we could, it would probably not be for all time. To take the most obvious example, we can not shield a system from the influence of gravity. At best, we can move systems to locations feeling less and less gravitational force, but we can never completely decouple a system from the gravitational field. Not only do we ignore the weak gravitational force when doing classical thermodynamics, but we also ignore less exotic matters, such as the walls in the standard gas in a box scenario. We can do this because the time it takes for a gas to reach equilibrium with itself is vastly shorter than the time it takes the gas plus walls system to reach equilibrium. For this reason we typically discount the effects of the box walls on the gas.

In this approximation many have thought there lies a possible solution to the problem of the direction of time. Indeed, many have thought herein lies a solution that *does not* change the laws of classical mechanics and *does not* allow for the nomological possibility of anti-thermodynamic behavior. In other words, advocates of this view seem to believe it embodies a third way.

The idea is to take advantage of what a random perturbation of the representative phase point would do to the evolution of a system. In phase space there is a tremendous asymmetry between the volume of points leading to equilibrium and points leading away from equilibrium. If the representative point of a system were knocked about randomly, then due to this asymmetry, it would be very probable that the system at any given time be on a trajectory leading toward equilibrium. Thus, if it could be argued that the earlier treatment of the statistical mechanics of ideal systems ignored a random perturber in the environment of the system, then one would seem to have a solution to our problems. Even if the perturbation were weak it would still have the desired effect. The weak 'random' previously ignored knocking of the environment is the sought after cause of the approach to equilibrium. Prima facie, this answer to the problem escapes the appeal to special initial conditions and the appeal to new laws.

But only prima facie. A number of criticisms have been leveled against this maneuver. One that seems on the mark is the observation that if classical mechanics is to be a universal theory, then the environment must be governed by the laws of classical mechanics as well. The environment is not some mechanism outside the governance of physical law, after all, and when we treat it too, the 'deus ex machina' -- the random perturber -- disappears. If we treat the gas-plus-the-container walls as a classical system, it is still governed by time-reversible laws that will cause the same problem as we met with the gas alone. At this point one sometimes sees the response that that combined system of gas plus walls has a neglected environment too, and so on, and so on, until we get to the entire universe. It is then questioned whether we have a right to expect laws to apply universally (Reichenbach 1956, 81ff). Or the point is made that we cannot write down the Hamiltonian for all the interactions a real system suffers, and so there will always be something 'outside' what is governed by the time-reversible Hamiltonian. Both of these points rely, we suspect, on an underlying instrumentalism about the laws of nature. Our problem only arises if we assume or pretend that the world literally is the way the theory says; dropping this assumption naturally 'solves' the problem. Rather than further address these responses, let us turn to the claim that this maneuver need not modify the laws of classical mechanics.

If one does not make the radical proclamation that physical law does not govern the environment, then it is easy to see that whatever law describes the perturber's behavior, it cannot be the laws of classical mechanics *if* the environment is to do the job required of it. A time-reversal noninvariant law, in contrast to the TRI laws of classical mechanics, must govern the external perturber. Otherwise we can in principle subject the whole system, environment plus system of interest, to a Loschmidt reversal. The system's velocities will reverse, as will the velocities of the millions of tiny perturbers. 'Miraculously', as if there were a conspiracy between the reversed system and the millions of 'anti-perturbers', the whole system will return to a time reverse of its original state. What is more, this reversal will be just as likely as the original process if the laws are TRI. A minimal criterion of adequacy, therefore, is that the random perturbers be time reversal *noninvariant*. But the laws of classical mechanics are TRI. Consequently, if this 'solution' is to succeed, it must exercise new laws and modify or supplement classical mechanics. (Since the perturbations need to be genuinely random and not merely unpredictable, and since classical mechanics is deterministic, the same sort of argument could be run with indeterminism instead of irreversibility. See Price 2002 for a diagnosis of why people have made this mistake, and also for an argument objecting to interventionism for offering a 'redundant' physical mechanism responsible for entropy increase.) [8.]

2.7 Quantum Mechanics

To the best of our knowledge, our world is fundamentally quantum mechanical, not classical mechanical. Does this change the situation? 'Maybe' is perhaps the best answer. Not surprisingly, answers to the question are affected by one's interpretation of quantum mechanics. Quantum mechanics suffers from the notorious measurement problem, a problem which demands one or another interpretation of the quantum formalism. These interpretations fall broadly into two types, depending on their view of the unitary evolution of the quantum state (e.g., evolution according to the Schroedinger equation): they either say that there is something more than the quantum state, or that the unitary evolution is not entirely correct.

The former are called ‘no-collapse’ interpretations while the latter are dubbed ‘collapse’ interpretations. This is not the place to go into the details of these interpretations, but we can still sketch the outlines of the picture painted by quantum mechanics (for more see Albert 1992).

Modulo some philosophical concerns about the meaning of time reversal (see Albert 2000, Callender 2000), the equation governing the unitary evolution of the quantum state is time reversal invariant. For interpretations that add something to quantum mechanics, this typically means that the resulting theory is time reversal invariant too (since it would be odd or even inconsistent to have one part of the theory invariant and the other part not). Since the resulting theory is time reversal invariant, it is possible to generate the problem of the direction of time just as we did with classical mechanics. While many details are altered in the change from classical to no-collapse quantum mechanics, the logical geography seems to remain the same.

Collapse interpretations are more interesting with respect to our topic. Collapses interrupt or outright replace the unitary evolution of the quantum state. To date, they have always done so in a time reversal *non*invariant manner. The resulting theory, therefore, is not time reversal invariant. This fact offers a potential escape from our problem: the transitions of type (2) in our above statement of the problem may not be lawful. And this has led many thinkers throughout the century to believe that collapses somehow explain the thermodynamic time asymmetry.

Mostly these postulated methods fail to provide what we want. We think gases relax to equilibrium even when they’re not measured by Bohrian observers or Wignerian conscious beings. This complaint is, admittedly, not independent of more general complaints about the adequacy of these interpretations. But perhaps because of these controversial features they have not been pushed very far in explaining thermodynamics.

More satisfactory collapse theories exist, however. One, commonly known as GRW, can describe collapses in a closed system -- no dubious appeal to observers outside the quantum system is required. Albert (1994; 2001) has extensively investigated the impact GRW would have on statistical mechanics and thermodynamics. GRW would ground a temporally asymmetric probabilistic tendency for systems to evolve toward equilibrium. Anti-thermodynamic behavior is not impossible according to this theory. Instead it is tremendously unlikely. The innovation of the theory lies in the fact that although entropy is overwhelmingly likely to increase toward the future, it is not also overwhelmingly likely to increase toward the past (because there are no dynamic backwards transition probabilities providied by the theory). So the theory does not suffer from a problem of the direction of time as stated above.

This does not mean, however, that it removes the need for something like the Past Hypothesis. GRW is capable of explaining why, given a present nonequilibrium state, later states should have higher entropy; and it can do this without also implying that earlier states have higher entropy too. But it does not explain how the universe ever got into a nonequilibrium state in the first place. As indicated before, some are not sure *what* would explain this fact, if anything, or whether it’s something we should even aspire to explain. The principal virtue GRW would bring to the situation, Albert thinks, is that it would solve or

bypass various troubles involving the nature of probabilities in statistical mechanics.

More detailed discussion of the impact quantum mechanics has on our problem can be found in Albert 2000, North 2002, Price 2002. But if our superficial review is correct, we can say that quantum mechanics will not obviate our need for a Past Hypothesis though it may well solve (on a GRW interpretation) at least one problem related to the direction of time.

2.8 Lawlike Initial Conditions?

Without some new physics that eliminates or explains the Past Hypothesis, or some satisfactory 'third way', it seems we are left with a bald posit of special initial conditions. Again, one can question whether there really is anything unsatisfactory about this (Sklar 1993; Callender 1997). But perhaps we were wrong in the first place to think of the Past Hypothesis as a contingent boundary condition. The question 'why these special initial conditions?' would be answered with 'it's physically impossible for them to be otherwise,' which is always a conversation stopper. Indeed, Feynman (1965, 116) speaks this way when explaining the statistical version of the second law.

Absent a particular understanding of laws of nature, there is perhaps not much to say about the issue. But given particular conceptions of lawhood, it is clear that various judgments about this issue follow naturally -- as we will see momentarily. However, let's acknowledge that this may be to get matters backwards. It might be said that we *first* ought to find out whether the boundary conditions *are* lawlike, and *then* devise a theory of law appropriate to the answer. To decide whether or not the boundary conditions are lawlike based merely on current philosophical theories of law is to prejudge the issue. Perhaps this objection is really evidence of the feeling that settling the issue based on one's conception of lawhood seems particularly unsatisfying. And it is hard to deny this. Even so, it is illuminating to have a brief look at the relationships between some conceptions of lawhood and the topic of special initial conditions.

For instance, if one agrees with Mill that from the laws one should be able to deduce everything and one considers the thermodynamic part of that 'everything,' then the special initial condition will be needed for such a deduction. The modern heir of this conception of lawhood, the one associated with Ramsey and Lewis (see Loewer 1994), sees laws as the axioms of the simplest, most powerful, consistent deductive system possible. It is likely that the specification of a special initial condition would emerge as an axiom in such a system, for such a constraint may well make the laws much simpler than they otherwise would be.

We should not expect the naïve regularity view of laws to follow suit, however. On this sort of account, roughly, if As always follow Bs, then it is a law of nature that A causes B. To avoid finding laws everywhere, however, this account needs to assume that As and Bs are instantiated plenty of times. But the initial conditions occur only once.

For more robust realist conceptions of law, it's difficult to predict whether the special initial conditions

will emerge as lawlike. Necessitarian accounts like Pargetter's 1984 maintain that it is a law that *P* in our world iff *P* obtains at every possible world joined to ours by a nomic accessibility relation. Without more specific information about the nature of the accessibility relations and the worlds to which we're related, one can only guess whether all of the worlds relative to ours have the same special initial conditions. Nevertheless some realist theories offer apparently prohibitive criteria, so they are able to make negative judgments. For instance, 'universalist' theories associated with Armstrong say that laws are relations between universals. Yet a constraint on initial conditions isn't in any natural way put in this form; hence it would seem the universalist theory would not consider this constraint lawlike.

Philosophical opinion is certainly divided. The problem is that a lawlike boundary condition lacks many of the features we ordinarily attribute to laws, e.g., multiple instances, governing temporal evolution, etc., yet different accounts of laws focus on different subsets of these features. When we turn to the issue at hand, what we find is the disagreement we expect.

3. The Problem of the Direction of Time II

A completely different problem going by the name 'problem of the direction of time' is the question of grounding various non-thermodynamic temporal asymmetries (to be described in detail below). In this problem, we take the thermodynamic arrow as given and use it to explain other temporally asymmetric features of the world, e.g., causation, knowledge. Boltzmann famously suggested that many of these asymmetries are given by the direction of entropy increase. And Reichenbach 1956 modified this to some of these temporal asymmetries being given by the direction of dominant entropy increase among all so-called "branch systems."

Sklar 1985 provides a useful discussion of this topic. He points out that conceiving of the reduction of these temporal asymmetries to that of the entropic arrow evades many of its obvious shortcomings if we conceive of it as a potential a posteriori scientific reduction of the kind now very familiar. The question is then whether it is so reduced (as for instance, the up-down plausibly reduces to the local gravitational gradient) or whether there is merely a correlation between the two (as, for example, there is between left-right and parity violations in high-energy particle physics).

The question is not easily answered partly due to vagueness about what is meant by both the concept to be reduced and the reducing concept. What temporal asymmetries are we concerned with, and exactly what kind of entropic relation do we intend?

The temporal asymmetries with which we are concerend are all the phenomena that we associate with the past and future directions being different. In addition to all of the temporal asymmetries from physics (thermodynamic arrow, electromagnetic arrow, Hubble expansion, etc.), there are a number of different asymmetries with which we are all familiar. The 'direction of time' might then be a broad umbrella covering the following:

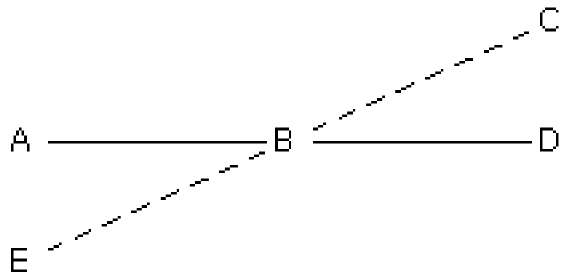
1. The psychological arrow. This controversial arrow is actually many different asymmetries. One, though much disputed, is that we seem to share a psychological sense of passage through time. Allegedly, we sense a moving ‘now’, the motion of the present as events are transformed from future to past. Another is that we have very different attitudes toward the past than toward the future. We dread future but not past headaches and prison sentences.

2. The mutability arrow. We feel the future is ‘open’ or indeterminate in a way the past is not. The past is closed, fixed for all eternity. Related to this, no doubt, is the feeling that our actions are essentially tied to the future and not the past. The future is mutable whereas the past is not.

3. The epistemological arrow. Although we believe that we know some facts about the future, the vast majority of propositions we claim to know about the past. I know that yesterday’s broken egg on the floor had a similar outline to Chile’s boundaries, but I have no idea what country tomorrow’s broken egg will look like. There are many more traces of events in the future than in the past. When I say something embarrassing, information representing that event is encoded on sound and light waves that form a continually increasing spherical shell in my future light-cone. I am potentially further embarrassed throughout my whole future lightcone. Yet in the backward lightcone stretching from the event there is little or no indication of the unfortunate event.

4. The explanation-causation-counterfactual arrow. This arrow is actually three, though it seems plausible that there are connections among them. Backwards causation may be physically possible, but if it is, it seems either to never happen or be exceedingly rare. Causes typically occur before their effects. Related to the causal asymmetry in some fashion or other is the asymmetry of explanation. Usually good explanations appeal to events in the past of the event to be explained, not to events in the future. It may be that this is just a prejudice that we ought to dispense with, but it is an intuition that we frequently have. Finally, and no doubt this is again related to the other two arrows as well as the mutability arrow, we -- at least naively -- believe the future depends counterfactually on the present in a way that we do not believe the past depends counterfactually on the present.

For example, consider a body moving uniformly from point *A* to point *C* in accord with Newton’s first law of motion.[9.] A force is impressed on the body at *B* and the body changes direction and proceeds uniformly towards *C*.



We will assume the body is a molecule travelling in a relative vacuum, and that the only trace left by the force is the altered path of the body. The solid lines in the diagram represent what we take to be the actual path of the body, the broken lines the alternative paths. Now consider two competing subjunctive conditionals:

> If no force had been impressed upon the body at *B*,
>
> (i) it would have moved uniformly in the right line *ABD*.
>
> (ii) it would have moved uniformly in the right line *EBC*.

The problem is to find an objective reason for our preference of (i). It seems that *AB* is co-tenable with the counterfactual antecedent. If the antecedent were true, it seems the body would have continued from *B* to *D*. But *BC* is also a leg of the actual path of the body, and to what do we appeal besides temporal asymmetry to reject *BC* as co-tenable with the counterfactual supposition? Perhaps after our intuitions have been tutored by physics we should say that either (i) or (ii) is correct. Or perhaps the asymmetry relies on thermodynamics, in which case the world described above is too bare to support our asymmetry.

Some authors -- particularly defenders of the tensed theory of time -- dismiss out of hand the idea of grounding the direction of time on the direction of material processes in time. But with so many asymmetric processes in the world, and with homo sapiens being just a part of this world, there are strong reasons to favor a connection between the two in many cases. But what is the connection?

Many authors have explicitly or implicitly proposed various ‘dependency charts’ that are supposed to explain which of the above arrows depend on which for their existence. Horwich 1987, for instance, argues for an explanatory relationship wherein the counterfactual arrow depends for its existence on the causal arrow, which depends on the arrow of explanation, which depends on the epistemological arrow, which in turn depends on the fork asymmetry that he associates with some chaotic conditions in the early universe. One can imagine other ways to plausibly arrange the dependency chart. Lewis 1979 thinks an alleged over-determination of traces grounds the asymmetry of counterfactuals and that this in turn grounds the rest. The chart one judges most appropriate will depend, to a large degree, upon one’s general philosophical stance on realism and Humeanism, etc., and one’s understanding of the above arrows.

Which chart is the correct one is not our concern here. Rather, returning to our main topic, the Boltzmann

entropic reduction of time-direction, we now have a somewhat clearer question: do any or all of the above temporal asymmetries depend for their existence upon the thermodynamic time-asymmetry? At the end of his 1979, for instance, Lewis hints that the asymmetry of traces is linked to the thermodynamic arrow, but he can offer no further explanation. Reichenbach 1956, Gruenbaum 1963, and Smart 1967 have developed entropic accounts of the knowledge asymmetry. Various people, for instance Dowe 1992, have tied the direction of causation to the entropy gradient. And some have also tied the psychological arrow to this gradient (for a discussion see Kroes 1985).

One can think of reasons for being quite pessimistic about any straightforward positive link between these temporal asymmetries and the entropy gradient. We really don't know how to bridge the gap between the thermodynamic arrow and the other arrows. And the gap is huge when you start thinking about the science of thermodynamics. Thermodynamics is a science with very precise and definite restrictions on the applicability of its concepts. A system has an entropy, for instance, only when it is thermally isolated and in equilibrium. Yet it is clear that our experience of the above temporal asymmetries carves up the world much differently than thermodynamics does. System A's doing f at time t might cause system B's doing g at time t* (where t* > t), yet A and B may not, and typically will not, have well-defined entropies.

The objections (see Earman 1974, Horwich 1987) to the entropic account of the knowledge asymmetry are worth recalling. The entropic account claimed that because we know there are many more entropy-increasing rather than entropy-decreasing systems in the world (or our part of it), we can infer when we see a low-entropy system that it was preceded and caused by an interaction with something outside the system. To take the canonical example, upon seeing a footprint in the sand, we can infer, due to its high order, that it was caused by something previously also of high (or higher) order, i.e, someone walking.

Though this brief sketch does not do justice to the entropic account, one can still see that it faces some very severe and basic challenges. First, do footprints on beaches have well-defined thermodynamic entropies? To describe the example we switched from low-entropy to high order, but the association between entropy and our ordinary concept of order is teneuous at best and usually completely misleading. To describe the range of systems about which we have knowledge, the account needs something broader than the thermodynamic entropy. But what? And why expect whatever it is to behave like entropy in some respects but not (in terms of its definability) in others? Second, the entropic account doesn't license the inference to a human being walking on the beach. All it tells you is that the grains of sand in the footprint interacted with its environment previously, which barely scratches the surface of our ability to tell detailed stories about what happened in the past. Third, even if we have a broader understanding of entropy, it still doesn't seem that this broader concept always works. Consider Earman's 1974 example of bomb destroying a city. From the destruction we may infer that a bomb went off; yet the bombed city does not have lower entropy than its surroundings or even any type of intuitively higher order than its surroundings.

Boltzmann's suggestion that the temporal asymmetries discussed above are explained by the direction of increasing entropy, though attractive at an abstract level, is hard to maintain when one looks at the details. Still, the more general idea, that these temporal asymmetries are due to the asymmetric behavior

of physical processes in our world (whatever their origin ,law or Past Hypothesis) as opposed to more metaphysical sources seems very plausible. Much work remains to be done on this problem.

Stanford Encyclopedia of Philosophy
Notes to Thermodynamic Asymmetry in Time

Notes

1. For a nice discussion of this point within the debate about scientific realism, see Psillos 1994.

2. A third version, inequivalent to both of the above, is Caratheodory's law. It states that in the neighborhood of any equilibrium state of a system there are states that are inaccessible by an adiabatic process. This considerably more abstract version of the second law forbids a more general type of process than the other formulations, but it does so at the cost of making the law less intuitive, since its relationship to the familiar types of thermodynamic processes is often quite convoluted.

3. The so-called Third Law is essentially Nernst's Theorem, which states that the entropy of every system at absolute zero can always be taken equal to zero. The third law thus allows one to calculate the absolute value of the entropy; however, this is not necessary for classical thermodynamics to work successfully. In addition, there is the so-called Zero-th Law that expresses the transitivity of equilibrium: if two bodies A and B are separately in equilibrium with a third body C, then A and B are in equilibrium with one another. Interestingly, this law follows from Kelvin and Caratheodory's formulations but not from Clausius' (see Pippard 1964, 95).

4. Quantum field theory and the so-called CPT theorem suggest that neutral kaon decay is not TRI. One might also worry about whether quantum mechanics is really TRI (Albert 2001; Callender 2000).

5. This should be contrasted with the arrows of time discussed in semiclassical quantum gravity, for example, the idea that quantum scattering processes in systems with black holes violate the CPT theorem.

6. That is, a case can be made that both the 'super-weak' and 'milli-weak' fields postulated to account for CP-violations are quite analogous in method to the postulation of the time-ordering field. See Sachs 1986, 236, and references therein.

7. Blatt 1959, Reichbach 1956, Redhead and Ridderbos 1999, and to some extent, Horwich 1974 are a few works charmed by this idea.

8. The confusion surrounding interventionism is especially bad in quantum mechanics. Coupled with one of the primary sources of confusion, the measurement problem, and various mistaken views conflating information and entropy, one encounters many misguided ideas. The mysterious loss of information

essential to the observation process, for instance, is frequently said to be the source of quantum mechanical collapses and also the direction of time. Partovi (1989; 1990) has a project along these lines that exploits much such confusion. The point of his project is to show that interactions with the environment bring about wave function reduction that in turn causes entropy increase. Since environmental noise is often interpreted as environmental decoherence in QM, the decoherence approach to quantum measurement is also said to explain time's arrow (Joos and Zeh 1985). But since decoherence respects the unitarity and reversibility of the Schroedinger evolution, it is hard to see how it could make itself immune to a Loschmidt reversal, and so, this approach would still need to posit special initial conditions.

9. This example is from Sanford 1979; but see also Reichenbach 1956, pp. 43-47.

Intertheory Relations in Physics

Many issues in the philosophy of science concern the nature of theories and certain relations that may obtain between them. Typically, one is interested in the degree to which a successor to a given theory "goes beyond" (both descriptively and explanatorily) the theory it succeeds. Most often these issues are framed in the context of *reductive* relations between theories. When does a theory T' reduce to a theory T? How is one to understand the nature of this reduction relation? Interestingly, there are two distinct, yet, related ways of understanding the reductive relationship between T and T'. Thomas Nickles noted this in a paper entitled "Two Concepts of Intertheoretic Reduction." On the one hand, there is the "philosopher's" sense of reduction on which the supplanted theory is said to reduce to the newer more encompassing theory. On the other hand, the "physicist's" sense of reduction puts things the other way. The newer, typically more refined theory is said to reduce to the older typically less encompassing theory in some sort of limit. These two senses of reduction will be discussed in turn.

---

1. Philosopher's Sense of Reduction

Most contemporary discussions of reductive relations between a pair of theories owe considerable debt to the work by Ernest Nagel. In *The Structure of Science*, Nagel asserts that "[r]eduction ... is the explanation of a theory or a set of experimental laws established in one area of inquiry, by a theory usually though not invariably formulated for some other domain." (Nagel, 1961, p. 338) The general schema here is as follows:

- T reduces T' just in case the laws of T' are derivable from those of T.

Showing how these derivations are possible for "paradigm" examples of intertheoretic reduction turns out

to be rather difficult.

Nagel distinguishes two types of reductions on the basis of whether or not the vocabulary of the reduced theory is a subset of the reducing theory. If it is---that is, if the reduced theory T' contains no descriptive terms not contained in the reducing theory T, and the terms of T' are understood to have approximately the same meanings that they have in T, then Nagel calls the reduction of T' by T "homogeneous." In this case, while the reduction may very well be enlightening in various respects, and is part of the "normal development of a science," most people believe that there is nothing terribly special or interesting from a philosophical point of view going on here. (Nagel, 1961, p. 339.)

Lawrence Sklar (1967, p. 110--111) points out that, from a historical perspective, this attitude is somewhat naive. The number of actual cases in the history of science where a genuine homogeneous reduction takes place are few and far between. Nagel, himself, took as a paradigm example of homogeneous reduction, the reduction of the Galilean laws of falling bodies to Newtonian mechanics. But, as Sklar points out, what actually can be derived from the Newtonian theory are *approximations* to the laws of the reduced Galilean theory. The approximations, of course, are strictly speaking *incompatible* with the actual laws and so, despite the fact that no concepts appear in the Galilean theory that do not also appear in the Newtonian theory, there is no deductive derivation of the *laws* of the one from the *laws* of the other. Hence, strictly speaking, there is no reduction on the deductive Nagelian model.

One way out of this problem for the proponent of Nagel-type reductions is to make a distinction between explaining a theory (or explaining the laws of a given theory) and explaining it away. (Sklar, 1967, pp. 112--113) Thus, we may still speak of reduction if the derivation of the approximations to the reduced theory's laws serves to account for why the reduced theory works as well as it does in its (perhaps more limited) domain of applicability. This is consonant with more sophisticated versions of Nagel-type reductions in which part of the very process of reduction involves revisions to the reduced theory. This process arises as a natural consequence of trying to deal with what Nagel calls "heterogeneous" reductions.

The task of characterizing reduction is more involved when the reduction is heterogenous---that is, when the reduced theory contains terms or concepts that do not appear in the reducing theory. Nagel takes, as a paradigm example of heterogeneous reduction, the (apparent) reduction of thermodynamics, or at least some parts of thermodynamics, to statistical mechanics.[1] For instance, thermodynamics contains the concept of temperature (among others) that is lacking in the reducing theory of statistical mechanics.

Nagel notes that "if the laws of the secondary science [the reduced theory] contain terms that do not occur in the theoretical assumptions of the primary discipline [the reducing theory] ... , the logical derivation of the former from the latter is *prima facie* impossible." (Nagel, 1961, p. 352) As a consequence, Nagel introduces two "necessary formal conditions" required for the reduction to take place:

1. *Connectability*. "Assumptions of some kind must be introduced which postulate suitable relations between whatever is signified by ‘A’ [the term to be reduced, that is, an element of the vocabulary of theory T'] and traits represented by theoretical terms already present in the primary [reducing] science."
2. *Derivability*. "With the help of these additional assumptions, all the laws of the secondary science, including those containing the term ‘A,’ must be logically derivable from the theoretical premises and their associated coordinating definitions in the primary discipline." (Nagel, 1961, pp. 353--354)

The connectability condition brings with it a number of interpretive problems. Exactly what is, or should be, the status of the "suitable relations," often called bridge "laws" or bridge hypotheses? Are they established by linguistic investigation alone? Are they factual discoveries? If the latter, what sort of necessity do they involve? Are they identity relations that are contingently necessary or will some sort of weaker relation, such as nomic coextensivity, suffice? Much of the philosophical literature on reduction addresses these questions about the status of the bridge laws.[2]

The consideration of certain examples lends plausibility to the idea, prevalent in the literature, that the bridge laws should be considered to express some kind of identity relation. For instance, Sklar notes that the reduction of the "theory" of physical optics to the theory of electromagnetic radiation proceeds by *identifying* one class of entities -- light waves -- with (part of) another class -- electromagnetic radiation. He says "... the place of correlatory laws [bridge laws] is taken by empirically established *identifications* of two classes of entities. Light waves are not correlated with electromagnetic waves, for they *are* electromagnetic waves." (Sklar, 1967, p. 120) In fact, if something like Nagelian reduction is going to work, it is generally accepted that the bridge laws should reflect the existence of some kind of synthetic identity.

Kenneth Schaffner calls the bridge laws "reduction functions." He too notes that they must be taken to reflect synthetic identities since, at least initially they require empirical support for their justification. "Genes were not discovered to be DNA via the analysis of *meaning*; important and difficult empirical research was required to make such an identification." (Schaffner, 1976. pp. 614--615)

Now one problem facing this sort of account was forcefully presented by Feyerabend in "Explanation, Reduction, and Empiricism." (Feyerabend, 1962) Consider the term "temperature" as it functions in classical thermodynamics. This term is defined in terms of Carnot cycles and is related to the strict, nonstatistical second law as it appears in that theory. The so-called reduction of classical thermodynamics to statistical mechanics, however, fails to identify or associate *nonstatistical* features in the reducing theory, statistical mechanics, with the nonstatistical concept of temperature as it appears in the reduced theory. How can one have a genuine reduction, if terms with their meanings fixed by the role they play in the reduced theory get identified with terms having entirely different meanings? Classical thermodynamics is not a statistical theory. The very possibility of finding a reduction function or bridge law that captures the concept of temperature and the strict, nonstatistical, role it plays in the thermodynamics seems impossible.

The plausibility of this argument, of course, depends on certain views about how meaning accrues to theoretical terms in a theory. However, just by looking at the historical development of thermodynamics one thing seems fairly clear. Most physicists, now, would accept the idea that our concept of temperature and our conception of other "exact" terms that appear in classical thermodynamics such as "entropy," need to be modified in light of the alleged reduction to statistical mechanics. Textbooks, in fact, typically speak of the theory of "statistical thermodynamics." The very process of "reduction" often leads to a corrected version of the reduced theory.

In fact, Schaffner and others have developed sophisticated Nagelian type schemas for reduction that explicitly try to capture these features of actual theory change. The idea is explicitly to include in the model, the "corrected reduced theory" such as statistical thermodynamics. Thus, Schaffner (1976, p. 618) holds that T reduces T' if and only if there is a corrected version of T', call it T'^* such that

1. The primitive terms of T'^* are associated via reduction functions (or bridge laws) with various terms of T.
2. T'^* is derivable from T when it is supplemented with the reduction functions specified in 1.
3. T'^* corrects T' in that it makes more accurate predictions than does T'.
4. T' is explained by T in that T' and T'^* are *strongly analogous* to one another, and T indicates why T' works as well as it does in its domain of validity.

Much work clearly is being done here by the intuitive conception of "strong analogy" between the reduced theory T' and the corrected reduced theory T'^*. In some cases, as suggested by Nickles and Wimsatt, the conception of strong analogy may find further refinement by appeal to what was referred to as the "physicists" sense of reduction.

2. Physicist's Sense of Reduction

Philosphical theories of reduction would have it that, say, quantum mechanics reduces classical mechanics through the derivation of the laws of classical physics from those of quantum physics. Most physicists would, on the other hand, speak of quantum mechanics reducing to classical mechanics in some kind of correspondence limit (e.g., the limit as Planck's constant ($h/2\pi$) goes to zero). Thus, the second type of intertheoretic reduction noted by Nickles fits the following schema:

Schema R: $\lim_{\varepsilon \to 0} T_f = T_c$

Here T_f is the typically newer, more fine theory, T_c is the typically older, coarser theory, and ε is a fundamental parameter appearing in T_f.

One must take the equality here with a small grain of salt. In those situations where **Schema R** can be said to hold, it is likely not the case that every equation or formula from T_f will yield a corresponding

equation of T_c .

Even given this caveat, the equality in **Schema R** can hold only if the limit is "regular." In such circumstances, it can be argued that it is appropriate to call the limiting relation a "reduction." If the limit in **Schema R** is singular, however, the schema fails and it is best to talk simply about intertheoretic relations.

One should understand the difference between regular and singular limiting relations as follows. If the solutions of the relevant formulae or equations of the theory T_f are such that for small values of ε they *smoothly* approach the solutions of the corresponding formulas in T_c, then **Schema R** will hold. For these cases we can say that the "limiting behavior" as $\varepsilon \to 0$ equals the "behavior in the limit" where $\varepsilon = 0$. On the other hand, if the behavior in the limit is of a *fundamentally different character* than the nearby solutions one obtains as $\varepsilon \to 0$, then the schema will fail.

A nice example illustrating this distinction is the following: Consider the quadratic equation $x^2 + x - 9\varepsilon = 0$. Think of ε as a small expansion or perturbation parameter. The equation has two roots for any value of ε as $\varepsilon \to 0$. In a well-defined sense, the solutions to this quadratic equation as $\varepsilon \to 0$ smoothly approach solutions to the "unperturbed" ($\varepsilon = 0$) equation $x^2 + x = 0$; namely, $x = 0, -1$. On the other hand, the equation $x^2\varepsilon + x - 9 = 0$ has two roots for any value of $\varepsilon > 0$ but has for the its "unperturbed" solution only one root; namely, $x = 9$. The equation suffers a reduction in order when $\varepsilon = 0$. Thus, the character of the behavior in the limit $\varepsilon = 0$ differs fundamentally from the character of its limiting behavior. Not all singular limits result from reductions in order of the equations. Nevertheless, these latter singular cases are much more prevalent than the former.

A paradigm case where a limiting reduction of the form **R** rather straightforwardly holds is that of classical Newtonian particle mechanics (NM) and the special theory of relativity (SR). In the limit where $(v/c)^2 \to 0$, SR reduces to NM. Nickles says "epitomizing [the intertheoretic reduction of SR to NM] is the reduction of the Einsteinian formula for momentum,

$$p = m_0 v / \sqrt{(1 - (v/c)^2)}$$

where m_0 is the rest mass, to the classical formula $p = m_0 v$ in the limit as $v \to 0$."[3] (Nickles, 1973, p. 182)

This is a regular limit---there are no singularities or "blowups" as the asymptotic limit is approached. As noted one way of thinking about this is that the exact solutions for small but nonzero values of $|\varepsilon|$ "smoothly [approach] the unperturbed or zeroth-order solution [ε set identically equal to zero] as $\varepsilon \to 0$." In the case where the limit is *singular* "the exact solution for $\varepsilon = 0$ is *fundamentally different in character* from the 'neighboring' solutions obtained in the limit $\varepsilon \to 0$." (Bender and Orszag, 1978, p. 324)

In the current context, one can express the regular nature of the limiting relation in the following way. The fundamental expression appearing in the Lorentz transformations of SR , can be expanded in a Taylor series as

$$1/\sqrt{(1-(v/c)^2)} = 1 - 1/2\,(v/c)^2 - 1/8\,(v/c)^4 - 1/16\,(v/c)^6 - \ldots$$

and so the limit is analytic. This means that (at least some) quantities or expressions of SR can be written as Newtonian or classical quantities plus an expansion of corrections in powers of $(v/c)^2$. So one may think of this relationship between SR and NM as a *regular* perturbation problem.

Examples like this have led some investigators to think of limiting relations as forming a kind of new rule of inference which would allow one to more closely connect the physicists' sense of reduction with that of the philosophers'. Fritz Rohrlich, for example, has argued that NM reduces (in the philosophers' sense) to SR because the *mathematical framework* of SR reduces (in the physicists' sense) to the *mathematical framework* of NM. The idea is that the mathematical framework of NM is "rigorously derived" from that of SR in a "derivation which involves limiting procedures." (Rohrlich, 1988, p. 303) Roughly speaking, for Rohrlich a "coarser" theory is reducible to a "finer" theory in the philosophers' sense of being rigorously deduced from the latter just in case the mathematical framework of the finer theory reduces in the physicists' sense to the mathematical framework of the coarser theory. In such cases, we will have a systematic explication of the idea of "strong analogy" to which Schaffner appeals in his model of philosophical reduction. The corrected theory T'^* in this context is the perturbed Newtonian theory as expressed in the Taylor expansion given above. The "strong analogy" between Newtonian theory T' and the corrected T'^* is expressed by the existence of the *regular* Taylor series expansion.

As noted the trouble with maintaining that this relationship between the philosophical and "physical" models of reduction holds generally is that far more often than not the limiting relations between the theories are *singular* and not regular. In such situations, **Schema R** fails to hold. Paradigm cases here include the relationships between classical mechanics and quantum mechanics, the ray theory of light and the wave theory, and thermodynamics and statistical mechanics of systems in critical states.

Intertheory Relations

It seems reasonable to expect something like philosophical reductions to be possible in those situations where **Schema R** holds. On the other hand, neither philosophical nor "physical" reduction seems possible when the limiting correspondence relation between the theories is singular. Perhaps in such cases it is best to speak simply of intertheoretic relations rather than reductions. It is here that much of philosophical and physical interest is to be found. This claim and the following discussion should not be taken to be anything like the received view among philosophers of science. Instead, it reflects the views of the author.

Nevertheless, here is a passage from a recent paper by Michael Berry which expresses a similar point of

view.

> Even within physical science, reduction between different levels of explanation is problematic--indeed, it is almost always so. Chemistry is supposed to have been reduced to quantum mechanics, yet people still argue over the basic question of how quantum mechanics can describe the shape of a molecule. The statistical mechanics of a fluid reduces to its thermodynamics in the limit of infinitely many particles, yet that limit breaks down near the critical point, where liquid and vapour merge, and where we never see a continuum no matter how distantly we observe the particles . . . . The geometrical (newtonian) optics of rays should be the limit of wave optics as the wavelength becomes negligibly small, yet . . . the reduction (mathematically similar to that of classical to quantum mechanics) is obstructed by singularities ... .
>
> My contention ... will be that many difficulties associated with reduction arise because they involve *singular limits*. These singularities have both negative and positive aspects: they obstruct the smooth reduction of more general theories to less general ones, but they also point to a great richness of borderland physics between theories. (Berry, forthcoming, p. 3)

When **Schema R** fails this is because the mathematics of the particular limit ($\varepsilon \to 0$) is singular. One can ask what, physically, is responsible for this mathematical singularity. In investigating the answer to this question one will often find that the mathematical blow-up reflects a physical impossibility. For instance, if **Schema R** held when T_f is the wave theory of light and T_c is the ray theory (geometrical optics), then one would expect to recover rays in the shortwave limit $\lambda \to 0$ of the wave theory. On the ray theory, rays are the carriers of energy. But in certain situations families of rays can focus on surfaces or lines called "caustics." These are not strange estoteric situations. In fact, rainbows are, to a first approximation, described by the focusing of sunlight on these surfaces following its refraction and reflection through raindrops. However, according to the ray theory, the intensity of the light on these focusing surfaces would be *infinite*. This is part of the physical reason for the mathematical singularities.

One is led to study the asymptotic domain in which the parameter ε in **Schema R** approaches 0. In the example above, this is the short wavelength limit. Michael Berry (1980,1990, 1994a, 1994b) has done much research on this and other asymptotic domains. He has found that in the asymptotic borderlands between such theories there emerge phenomena whose explanation requires in some sense appeal to a third intermediate theory. The emergent structures (the rainbow itself is one of them) are not fully explainable either in terms of the finer wave theory or in terms of the ray theory alone. Instead, aspects of both theories are required for a full understanding of these emergent phenomena.

This fact calls into question certain received views about the nature of intertheoretic relations. The wave theory, for example, is surely the fundamental theory. Nevertheless, these considerations seem to show that that theory is itself explanatorily deficient. There are phenomena within its scope whose explanations require reference to structures that exist only in the superseded, *false*, ray theory. A similar

situation arises in the asymptotic domain between quantum mechanics and classical mechanics where Planck's constant can be considered asymptotically small.

There is much here worthy of further philosophical study. See (Batterman 1993, 1995, and forthcoming) for the beginnings of some work in this direction.

Notes to Intertheory Relations in Physics

Notes

1. That this is a paradigm example of reduction practically has the status of dogma in the philosophical literature on reduction. Unfortunately, this is entirely misguided. See Sklar's *Physics and Chance* for an extended discussion.

2. For a good introduction to the subtleties involved see Sklar, 1967, pp. 118--121.

3. It is best to think of this limit as $(v/c)^2 \to 0$ since $(v/c)^2$ is a dimensionless quantity and so this limit will not depend on the units used to measure the velocity.

Philosophy of Statistical Mechanics

Statistical mechanics was the first foundational physical theory in which probabilistic concepts and probabilistic explanation played a fundamental role. For the philosopher it provides a crucial test case in which to compare the philosophers' ideas about the meaning of probabilistic assertions and the role of probability in explanation with what actually goes on when probability enters a foundational physical theory. The account offered by statistical mechanics of the asymmetry in time of physical processes also plays an important role in the philosopher’s attempt to understand the alleged asymmetries of causation and of time itself.

---

1. Historical Sketch

From the seventeenth century onward it was realized that material systems could often be described by a small number of descriptive parameters that were related to one another in simple lawlike ways. These parameters referred to geometric, dynamical and thermal properties of matter. Typical of the laws was the ideal gas law that related product of pressure and volume of a gas to the temperature of the gas.

It was soon realized that a fundamental concept was that of equilibrium. Left to themselves systems would change the values of their parameters until they reached a state where no further changes were observed, the equilibrium state. Further, it became apparent that this spontaneous approach to equilibrium was a time-asymmetric process. Uneven temperatures, for example, changed until temperatures were

uniform. This same "uniformization" process held for densities.

Profound studies by S. Carnot of the ability to extract mechanical work out of engines that ran by virtue of the temperature difference between boiler and condenser led to the introduction by R. Clausius of one more important parameter describing a material system, its entropy. How was the existence of this simple set of parameters for describing matter and the lawlike regularities connecting them to be explained? What accounted for the approach to equilibrium and its time asymmetry? That the heat content of a body was a form of energy, convertible to and from mechanical work formed one fundamental principle. The inability of an isolated system to spontaneously move to a less orderly state, to lower its entropy, constituted another. But why were these laws true?

One approach, that of P. Duhem and E. Mach and the "energeticists," was to insist that these principles were autonomous phenomenological laws that needed no further grounding in some other physical principles. An alternative approach was to claim that the energy in a body stored as heat content was an energy of motion of some kind of hidden, microscopic constituents of the body, and to insist that the laws noted, the thermodynamic principles, needed to be accounted for out of the constitution of the macroscopic object out of its parts and the fundamental dynamical laws governing the motion of those parts. This is the kinetic theory of heat.

Early work on kinetic theory by W. Herepath and J. Waterston was virtually ignored, but the work of A. Krönig made kinetic theory a lively topic in physics. J. C. Maxwell made a major advance by deriving from some simple postulates a law for the distribution of velocities of the molecules of a gas when it was in equilibrium. Both Maxwell and L. Boltzmann went further, and in different, but related, ways derived an equation for the approach to equilibrium of a gas. The equilibrium distribution earlier found by Maxwell could then be shown to be a stationary solution of this equation.

This early work met with vigorous objections. H. Poincaré had proven a recurrence theorem for bounded dynamical systems that seemed to contradict the monotonic approach to equilibrium demanded by thermodynamics. Poincaré's theorem showed that any appropriately bounded system in which energy was conserved would of necessity, over an infinite time, return an infinite number of times to states arbitrarily close to the initial dynamical state in which the system was started. J. Loschmidt argued that the time irreversibility of thermodynamics was incompatible with the symmetry under time reversal of the classical dynamics assumed to govern the motion of the molecular constituents of the object.

Partly driven by the need to deal with these objections explicitly probabilistic notions began to be introduced into the theory by Maxwell and Boltzmann. Both realized that equilibrium values for quantities could be calculated by imposing a probability distribution over the microscopic dynamical states compatible with the constraints placed on the system, and identifying the observed macroscopic values with averages over quantities definable from the microscopic states using that probability distribution. But what was the physical justification for this procedure?

Both also argued that the evolution toward equilibrium demanded in the non-equilibrium theory could

also be understood probabilistically. Maxwell, introducing the notion of a "demon" who could manipulate the microscopic states of a system, argued that the law of entropic increase was only probabilistically valid. Boltzmann offered a probabilistic version of his equation describing the approach to equilibrium. Without considerable care, however, the Boltzmannian picture can still appear contrary to the objections from recurrence and reversibility interpreted in a probabilistic manner.

Late in his life Boltzmann responded to the objections to the probabilistic theory by offering a time-symmetric interpretation of the theory. Systems were probabilistically almost always close to equilibrium. But transient fluctuations to non-equilibrium states could be expected. Once in a non-equilibrium state it was highly likely that both after and before that state the system was closer to equilibrium. Why then did we live in a universe that was not close to equilibrium? Perhaps the universe was vast in space and time and we lived in a "small" non-equilibrium fluctuational part of it. We could only find ourselves in such an "improbable" part, for only in such a region could sentient beings exist. Why did we find entropy increasing toward the future and not toward the past? Here the answer was that just as the local direction of gravity defined what we meant by the downward direction of space, the local direction in time in which entropy was increasing fixed what we took to be the future direction of time.

In an important work (listed in the bibliography), P. and T. Ehrenfest also offered a reading of the Boltzmann equation of approach to equilibrium that avoided recurrence objections. Here the solution of the equation was taken to describe not "the overwhelmingly probable evolution" of a system, but, instead, the sequence of states that would be found overwhelmingly dominant at different times in a collection of systems all started in the same non-equilibrium condition. Even if each individual system approximately recurred to its initial conditions, this "concentration curve" could still show monotonic change toward equilibrium from an initial non-equilibrium condition.

Many of the philosophical issues in statistical mechanics center around the notion of probability as it appears in the theory. How are these probabilities to be understood? What justified choosing one probability distribution rather than another? How are the probabilities to be used in making predictions within the theory? How are they to be used to provide explanations of the observed phenomena? And how are the probability distributions themselves to receive an explanatory account? That is, what is the nature of the physical world that is responsible for the correct probabilities playing the successful role that they do play in the theory?

2. Philosophers on Probability and Statistical Explanation

Philosophers concerned with the interpretation of probability are usually dealing with the following problem: Probability is characterized by a number of formal rules, the additivity of probabilities for disjoint sets of possibilities being the most central of these. But what ought we to take the formal theory to be a theory of? Some interpretations are "objectivist," taking probabilities to be, possibly, frequencies of outcomes, or idealized limits of such frequencies or perhaps measures of "dispositions" or

"propensities" of outcomes in specified test situations.

Other interpretations are "subjectivist," taking probabilities to be measures of "degrees of belief," perhaps evidenced in behavior in situations of risk by choices of available lotteries over outcomes. Still another interpretation reads probabilities as measures of a kind of "partial logical entailment" among propositions.

Although subjectivist (or, rather, logical) interpretations of probability in statistical mechanics have been proffered (by E. Jaynes, for example), most interpreters of the theory opt for an objectivist interpretation of probability. This still leaves open, however, important questions about just what "objective" feature the posited probabilities of the theory are and how nature contrives to have such probabilities evinced in its behavior.

Philosophers dealing with statistical explanation have generally focussed on everyday uses of probability in explanation, or the use of probabilistic explanations in such disciplines as the social sciences. Sometimes it has been suggested that to probabilistically explain an outcome is to show it likely to have occurred given the background facts of the world. In other cases it is suggested that to explain an outcome probabilistically is to produce facts which raise the probability of that outcome over what it would have been those facts being ignored. Still others suggest that probabilistic explanation is showing an event to have been the causal outcome of some feature of the world characterized by a probabilistic causal disposition.

The explanatory patterns of non-equilibrium statistical mechanics place the evolution of the macroscopic features of matter in a pattern of probabilities over possible microscopic evolutions. Here the types of explanation offered do fit the traditional philosophical models. The main open questions concern the explanatory grounds behind the posited probabilities. In equilibrium theory, as we shall see, the statistical explanatory pattern has a rather different nature.

3. Equilibrium Theory

The standard method for calculating the properties of an energetically isolated system in equilibrium was initiated by Maxwell and Boltzmann and developed by J. Gibbs as the microcanonical ensemble. Here a probability distribution is imposed over the set of microscopic states compatible with the external constraints imposed on the system. Using this probability distribution, average values of specified functions of the microscopic conditions of the gas (phase averages) are calculated. These are identified with the macroscopic conditions. But a number of questions arise: Why this probability distribution? Why average values for macroscopic conditions? How do phase averages related to measured features of the macroscopic system?

Boltzmann thought of the proper average values to identify with macroscopic features as being averages over time of quantities calculable from microscopic states. He wished to identify the phase averages with such time averages. He realized that this could be done if a system started in any microscopic state

eventually went through all the possible microscopic states. That this was so became known as the ergodic hypothesis. But it is provably false on topological and measure theoretic grounds. A weaker claim, that a system started in any state would go arbitrarily close to each other microscopic state is also false, and even if true would not do the job needed.

The mathematical discipline of ergodic theory developed out of these early ideas. When can a phase average be identified with a time average over infinite time? G. Birkhoff (with earlier results by J. von Neumann) showed that this would be so for all but perhaps a set of measure zero of the trajectories (in the standard measure used to define the probability function) if the set of phase points was metrically indecomposable, that is if it could not be divided into more than one piece such that each piece had measure greater than zero and such that a system started in one piece always evolved to a system in that piece.

But did a realistic model of a system ever meet the condition of metric indecomposability? What is needed to derive metric indecomposability is sufficient instability of the trajectories so that the trajectories do not form groups of non-zero measure which fail to wander sufficiently over the entire phase region. The existence of a hidden constant of motion would violate metric indecomposability. After much arduous work, culminating in that of Ya. Sinai, it was shown that some "realistic" models of systems, such as the model of a gas as "hard spheres in a box," conformed to metric indecomposability. On the other hand another result of dynamical theory, the Kolmogorov-Arnold-Moser (KAM) theorem shows that more realistic models (say of molecules interacting by means of "soft" potentials) are likely not to obey ergodicity in a strict sense. In these cases more subtle reasoning (relying on the many degrees of freedom in a system composed of a vast number of constituents) is also needed.

If ergodicity holds what can be shown? It can be shown that for all but a set of measure zero of initial points, the time average of a phase quantity over infinite time will equal its phase average. It can be shown that for any measurable region the average time the system spends in that region will be proportional to the region's size (as measured by the probability measure used in the microcanonical ensemble). A solution to a further problem is also advanced. Boltzmann knew that the standard probability distribution was invariant under time evolution given the dynamics of the systems. But how could we know that it was the only such invariant measure? With ergodicity we can show that the standard probability distribution is the only one that is so invariant, at least if we confine ourselves to probability measures that assign probability zero to every set assigned zero by the standard measure.

We have, then, a kind of "transcendental deduction" of the standard probability assigned over microscopic states in the case of equilibrium. Equilibrium is a time-unchanging state. So we demand that the probability measure by which equilibrium quantities are to be calculated be stationary in time as well. If we assume that probability measures assigning non-zero probability to sets of states assigned zero by the usual measure can be ignored, then we can show that the standard probability is the only such time invariant probability under the dynamics that drives the individual systems from one microscopic state to another.

As a full "rationale" for standard equilibrium statistical mechanics, however, much remains questionable.

There is the problem that strict ergodicity is not true of realistic systems. There are many problems encountered if one tries to use the rationale as Boltzmann hoped to identify phase averages with measured quantities relying on the fact that macroscopic measurements take "long times" on a molecular scale. There are the problems introduced by the fact that all of the mathematically legitimate ergodic results are qualified by exceptions for "sets of measure zero." What is it physically that makes it legitimate to ignore a set of trajectories just because it has measure zero in the standard measure? After all, such neglect leads to catastrophically wrong predictions when there really are hidden, global constants of motion. In proving the standard measure uniquely invariant, why are we entitled to ignore probability measures that assign non-zero probabilities to sets of conditions assigned probability zero in the standard measure? After all, it was just the use of that standard measure that we were trying to justify in the first place.

In any case, equilibrium theory as an autonomous discipline is misleading. What we want, after all, is a treatment of equilibrium in the non-equilibrium context. We would like to understand how and why systems evolve from any initially fixed macroscopic state, taking equilibrium to be just the "end point" of such dynamic evolution. So it is to the general account of non-equilibrium we must turn if we want a fuller understanding of how this probabilistic theory is functioning in physics.

4. Non-Equilibrium Theory

Boltzmann provided an equation for the evolution of the distribution of the velocities of particles from a non-equilibrium initial state for dilute gases, the Boltzmann equation. A number of subsequent equations have been found for other types of systems, although generalizing to, say, dense gases has proven intractable. All of these equations are called kinetic equations.

How may they be justified and explained? In the discussions concerning the problem of irreversibility that ensued after Boltzmann's work, attention was focussed on a fundamental assumption he made: the hypothesis with regard to collision numbers. This time-asymmetrical assumption posited that the motions of the molecules in a gas were statistically uncorrelated prior to the molecules colliding. In deriving any of the other kinetic equations a similar such posit must be made. Some general methods for deriving such equations are the master equation approach and an approach that relies upon coarse-graining the phase space of points representing the micro-states of the system into finite cells and assuming fixed transition probabilities from cell to cell (Markov assumption). But such an assumption was not derived from the underlying dynamics of the system, and, for all they knew so far, might have been inconsistent with that dynamics.

A number of attempts have been made to do without such an assumption and to derive the approach to equilibrium out of the underlying dynamics of the system. Since that dynamics is invariant under time reversal and the kinetic equations are time asymmetric, time asymmetry must be put into the explanatory theory somewhere.

One approach to deriving the kinetic equations relies upon work which generalizes ergodic theory.

Relying upon the instability of trajectories, one tries to show that a region of phase points representing the possible micro-states for a system prepared in a non-equilibrium condition will, if the constraints are changed, eventually evolve into a set of phase points that is "coarsely" spread over the entire region of phase space allowed by the changed constraints. The old region cannot "finely" cover the new region by a fundamental theorem of dynamics (Liouville's theorem). But, in a manner first described by Gibbs, it can cover the region in a coarse-grained sense. To show that a collection of points will spread in such a way (in the infinite time limit at least) one tries to show the system possessed of an appropriate "randomization" property. In order of increasing strength such properties include weak-mixing, mixing, being a K system or being a Bernoulli system. Other, topological as opposed to measure-theoretic, approaches to this problem exist as well.

As usual, many caveats apply. Can the system really be shown to have such a randomizing feature (in the light of the KAM theorem, for example)? Are infinite time limit results relevant to our physical explanations? If the results are finite time, are they relativized in the sense of saying that they only hold for some coarse partitionings of the system rather than to those of experimental interest?

Most importantly, mixing and its ilk cannot be the whole story. All the results of this theory are time symmetric. To get time asymmetric results, and to get results that hold in finite times and which show evolution in the manner described by the kinetic equation over those finite times, requires an assumption as well about how the probability is to be distributed over the region of points allowed as representing the system at the initial moment.

What must that probability assumption look like and how may it be justified? These questions were asked, and partly explored, by N. Krylov. Attempts at rationalizing this initial probability assumption have ranged from Krylov's own suggestion that it is the result of a non-quantum "uncertainty" principle founded physically on the modes by which we prepare systems, to the suggestion that it is the result of an underlying stochastic nature of the world described as in the Ghirardi-Rimini-Weber approach to understanding measurement in quantum mechanics. The status and explanation of the initial probability assumption remains the central puzzle of non-equilibrium statistical mechanics.

There are other approaches to understanding the approach to equilibrium at variance with the approaches that rely on mixing phenomena. O. Lanford, for example, has shown that for an idealized infinitely dilute gas one can show, for very small time intervals, an overwhelmingly likely behavior of the gas according to the Boltzmann equation. Here the interpretation of that equation by the Ehrenfests, the interpretation suitable to the mixing approach, is being dropped in favor of the older idea of the equation describing the overwhelmingly probable evolution of a system. This derivation has the virtue of rigorously generating the Boltzmann equation, but at the cost of applying only to one severely idealized system and then only for a very short time (although the result may be true, if unproven, for longer time scales). Once again an initial probability distribution is still necessary for time asymmetry.

5. Irreversibility

The thermodynamic principles demand a world in which physical processes are asymmetric in time. Entropy of an isolated system may increase spontaneously into the future but not into the past. But the dynamical laws governing the motion of the micro-constituents are, at least on the standard views of those laws as being the usual laws of classical or quantum dynamics, time reversal invariant. Introducing probabilistic elements into the underlying theory still does not by itself explain where time asymmetry gets into the explanatory account. Even if, following Maxwell, we take the Second Law of thermodynamics to be merely probabilistic in its assertions, it remains time asymmetric.

Throughout the history of the discipline suggestions have often been made to the effect that some deep, underlying dynamical law itself introduces time asymmetry into the motion of the micro-constituents.

Other proposals take the entropic change of a system to be mediated by an actually uneliminable "interference" into the system of random causal influences from outside the system. It is impossible, for example, to genuinely screen the system from subtle gravitational influences from the outside. The issue of the role of external interference in the apparently spontaneous behavior of what is idealized as an isolated system has been much discussed. Here the existence of special systems (such as spin echo systems encountered in nuclear magnetic resonance) plays a role in the arguments. For these systems seem to display spontaneous approach to equilibrium when isolated, yet can have their apparent entropic behavior made to "go backward" with an appropriate impulse from out side the system. This seems to show entropic increase without the kind of interference from the outside that genuinely destroys the initial order implicit in the system. In any case, it is hard to see how outside interference would do the job of introducing time asymmetry unless such asymmetry is put in "by hand" in characterizing that interference.

It was Boltzmann who first proposed a kind of "cosmological" solution to the problem. As noted above he suggested a universe overall close to equilibrium with "small" sub-regions in fluctuations away from that state. In such a sub-region we would find a world far from equilibrium. Introducing the familiar time-symmetric probabilistic assumptions, it becomes likely that in such a region one finds states of lower entropy in one time direction and states of higher entropy in the other. Then finish the solution by introducing the other Boltzmann suggestion that what we mean by the future direction of time is fixed as that direction of time in which entropy is increasing.

Current cosmology sees quite a different universe than that posited by Boltzmann. As far as we can tell the universe as a whole is in a highly non-equilibrium state with parallel entropic increase into the future everywhere. But the structure of the cosmos as we know it allows for an alternative solution to the problem of the origin of time asymmetry in thermodynamics. The universe seems to be spatially expanding, with an origin some tens of billions of years ago in an initial singularity, the Big Bang. Expansion, however, by itself does not provide the time asymmetry needed for thermodynamics, for an expanding universe with static or decreasing entropy is allowed by physics. Indeed, in some cosmological models in which the universe contracts after expanding, it is usually, though not always, assumed that even in contraction entropy continues to increase.

The source of entropic asymmetry is sought, rather, in the physical state of the world at the Big Bang.

Matter "just after" the Big Bang is usually posited to be in a state of maximum entropy – to be in thermal equilibrium. But this does not take account of the structure of "space itself," or, if you wish, of the way in which the matter is distributed in space and subject to the universal gravitational attraction of all matter for all other matter. A world in which matter is distributed with uniformity is one of low entropy. A high entropy state is one in which we find a clustering of matter into dense regions with lots of empty space separating these regions. This deviation from the usual expectation – spatial uniformity as the state of highest entropy – is due to the fact that gravity, unlike the forces governing the interaction of molecules in a gas for example, is a purely attractive force.

One can then posit an initial "very low entropy" state for the Big Bang, with the spatial uniformity of matter providing an "entropic resevoir." As the universe expands, matter goes from a uniformly distributed state with temperature also uniform to one in which matter is highly clumped into hot stars in an environment of cold empty space. One then has the universe as we know it, with its thermally highly non-equilibrium condition. "Initial low entropy," then, will be a state in the past not (as far as we know) matched by any singularity of any kind, much less one of low entropy, in the future. If one conditionalizes on that initial low entropy state one then gets, using the time symmetric probabilities of statistical mechanics, a prediction of a universe whose entropy increased in time.

But it is not, of course, the entropy of the whole universe with which the Second Law is concerned, but, rather, that of "small" systems temporarily energetically isolated from their environments. One can argue, in a manner tracing back to H. Reichenbach, that the entropic increase of the universe as a whole will lead, again using the usual time symmetric probabilistic posits, to a high probability that a random "branch system" will show entropic increase parallel to that of the universe and parallel to that of other branch systems. Most of the arguments in the literature that this will be so are flawed, but the inference is reasonable nonetheless.

Positing initial low entropy for the Big Bang gives rise to its own set of "philosophical" questions: Given the standard probabilities in which high entropy is overwhelmingly probable, how could we explain the radically "unexpected" low entropy of the initial state? Indeed, can we apply probabilistic reasoning appropriate for systems in the universe as we know it to an initial state for the universe as a whole? The issues here are reminiscent of the old debates over the teleological argument for the existence of God.

6. The Reduction(?) of Thermodynamics to Statistical Mechanics

It comes as no surprise that the relationship of the older thermodynamic theory to the new statistical mechanics on which it is "grounded" is one of some complexity.

The older theory had no probabilistic qualifications to its laws. But as Maxwell was clearly aware, it could not then be "exactly" true if the new probabilistic theory correctly described the world. One can either keep the thermodynamic theory in its traditional form and carefully explicate the relationship its

principles bear to the newer probabilistic conclusions, or one can, as has been done in deeply interesting ways, generate a new "statistical thermodynamics" that imports into the older theory probabilistic structure.

Conceptually the relationship of older to newer theory is quite complex. Concepts of the older theory (volume, pressure, temperature, entropy) must be related to the concepts of the newer theory (molecular constitution, dynamical concepts governing the motion of the molecular constituents, probabilistic notions characterizing either the states of an individual system or distributions of states over an imagined ensemble of systems subject to some common constraints).

A single term of the thermodynamic theory such as ‘entropy’ will be associated with a wide variety of concepts defined in the newer account. There is, for example, Boltzmann entropy which is the property of a single system defined in terms of the spatial and momentum distribution of its molecules. On the other hand there are the Gibbs'entropies, definable out of the probability distribution over some Gibbsian ensemble of systems. Adding even more complications there is, for example, Gibbs' fine grained entropy which is defined by the ensemble probability alone and is very useful in characterizing equilibrium states and Gibbs' coarse grained entropy whose definition requires some partitioning of the phase space into finite cells as well as the original probability distribution and which is a useful concept in characterizing approach to equilibrium from the ensemble perspective. In addition to these notions which are measure theoretic in nature, there are topological notions which can play the role of a kind of entropy as well.

Nothing in this complexity stands in the way of claiming that statistical mechanics describes the world in a way that explains why thermodynamics works and works as well as it does. But the complexity of the inter-relationship between the theories should make the philosopher cautious in using this relationship as a well understood and simple paradigm of inter-theoretic reduction.

It is of some philosophical interest that the relationship of thermodynamics to statistical mechanics shows some similarity to aspects uncovered in functionalist theories of the mind-body relationship. Consider, for example, the fact that systems of very different physical constitutions (say a gas made up of molecules interacting by means of forces on the one hand and on the other hand radiation whose components are energetically coupled wave lengths of light) can share thermodynamic features. They can, for example, be at the same temperature. Physically this means that the two systems, if initially in equilibrium and then energetically coupled, will retain their original equilibrium conditions. The parallel with the claim that a functionally defined mental state (a belief, say) can be instantiated in a wide variety of physical devices is clear.

7. The Direction of Time

We have noted that it was Boltzmann who first suggested that our very concept of the future direction of time was fixed by the direction in time in which entropy was increasing in our part of the universe. Numerous authors have followed up this suggestion and the "entropic" theory of time asymmetry remains a much debated topic in the philosophy of time.

We must first ask what the theory is really claiming. In a sensible version of the theory there is no claim being made to the effect that we find out the time order of events by checking the entropy of systems and taking the later event as the one in which some system has its higher entropy. The claim is, rather, that it is the facts about the entropic asymmetry of systems in time that "ground" the phenomena that we usually think of as marking out the asymmetrical nature of time itself.

What are some features whose intuitive temporal asymmetry we think of as, perhaps, "constituting" the asymmetrical nature of time? There are asymmetries of knowledge: We have memories and records of the past, but not of the future. There are asymmetries of determination: We think of causation as going from past through present to future, and not of going the other way round. There are asymmetries of concern: We may regret the past, but we anxiously anticipate the future. There are alleged asymmetries of "determinateness" of reality: It is sometimes claimed that past and present have determinate reality, but that the future, being a realm of mere possibilities, has no such determinate being at all.

The entropic theory in its most plausible formulation is a claim to the effect that we can explain the origin of all of these intuitive asymmetries by referring to fact about the entropic asymmetry of the world.

This can be best understood by looking at the very analogy used by Boltzmann: the gravitational account of up and down. What do we mean by the downward direction at a spatial location? All of the phenomena by which we intuitively identify the downward direction (as the direction in which rocks fall, for example) receive an explanation in terms of the spatial direction of the local gravitational force. Even our immediate awareness of which direction is down is explainable in terms of the effect of gravity on the fluid in our semi-circular canals. It comes as no shock to us at all that "down" for Australia is in the opposite direction as "down" for Chicago. Nor are we dismayed to be told that in outer space, far from a large gravitating object such as the Earth, there is no such thing as the up-down distinction and no direction of space which is the downward direction.

Similarly the entropic theorist claims that it is the entropic features that explain the intuitive asymmetries noted above, that in regions of the universe in which the entropic asymmetry was counter-directed in time the past-future directions of time would be opposite, and that in a region of the universe without an entropic asymmetry neither direction of time would count as past or as future.

The great problem remains in trying to show that the entropic asymmetry is explanatorily adequate to account for all the other asymmetries in the way that the gravitational asymmetry can account for the distinction of up and down. Despite many interesting contributions to the literature on this, the problem remains unresolved.

Bibliography

A comprehensive treatment of the issues from a philosophical perspective is Sklar 1993. Of important historical interest is Reichenbach 1956. An accessible and up-to-date discussion of the fundamental

issues is Albert 2000. Additional philosophical discussion is in Guttman 1999. A spirited defense of the initial low entropy approach to time asymmetry is Price 1996. English translations of many original fundamental papers are in Brush 1965. Brush 1976 provides an historical treatment of the development of the theory. Two foundational works that are essential are Gibbs 1960 and Ehrenfest and Ehrenfest 1959.

Backward Causation

Sometimes also called retro-causation. A common feature of our world seems to be that in all cases of causation, the cause and the effect are placed in time so that the cause precedes its effect temporally. Our normal understanding of causation assumes this feature to such a degree that we intuitively have great difficulty imagining things differently. The notion of backward causation, however, stands for the idea that the temporal order of cause and effect is a mere contingent feature and that there may be cases where the cause is causally prior to its effect but where the temporal order of the cause and effect is reversed with respect to normal causation, i.e. there may be cases where the effect temporally, but not causally, precedes its cause.

The idea of backward causation should not be confused with that of time travel. These two notions are related to the extent that both agree that it is possible to causally affect the past. The difference, however, is that time travel involves a causal loop whereas backward causation does not. Causal loops for their part can only occur in a universe in which one has closed time-like curves. In contrast, backward causation may take place in a world where there are no such closed time-like curves. In other words, an ordinary system *S* taking part in time travel would preserve the temporal order of its proper time during its travel, it would keep the same time sense during its entire flight (a watch measuring *S*'s proper time would keep moving clockwise); but if the same system *S* were to become involved in a process of backward causation, the order of its proper time would have to reverse in the sense that the time sense of the system would become opposite of what it was before its back-in-time travel (the watch will start to move counter-clockwise). So neither backward causation nor time travel logically entails each other and time travel is distinct from back-in-time travel.

1. History

The philosophical debate about backward causation is relatively new. Only little consideration of the problem can be found in the philosophical literature before Michael Dummett and Anthony Flew initiated their discussion in the mid 1950s. The reason for this is twofold. No empirical phenomena seem to demand a notion of backward causation for our understanding of them. And for a long time it was thought that such a notion involved either a contradiction in terms or a conceptual impossibility. David Hume's definition of the cause as the one of two events that happens before the other thus rules out that the cause can happen after its effect. Moreover, according to Kant's idea of synthetic a priori truth the claim that the cause temporally precedes its effect was considered to state such a truth. In 1954 Michael Dummett and Anthony Flew had a discussion about whether an effect can precede its cause. Dummett defended the idea whereas Flew argued that it involved contradictions in terms.

Two years later, Max Black (1956) presented an argument against backward causation, which became known as the bilking argument, and later attempts to meet the argument seemed to generate all kinds of paradoxes. Imagine *B* to be earlier than *A*, and let *B* be the alleged effect of *A*. Thus we assume that *A* causes *B* even though *A* is later than *B*. The idea behind the bilking argument is that whenever *B* has occurred, it is possible, in principle, to intervene in the course of events and prohibit *A* from occurring. But if this is the case, *A* cannot be the cause of *B*; hence, we cannot have backward causation. Since then philosophers have debated the effectiveness of the bilking argument in particular and, in general, the validity and the soundness of the concept of backward causation.

In the 1960s and 1970s, physicists began to discuss the possibilities of particles travelling with a speed greater than light, the so-called tachyons, and as a consequence a similar debate about paradoxes involving backward causation arose among them. In case superluminal particles, like tachyons, exist and could be used to generate signals, it seemed possible to communicate with the past because tachyons going forward in time with respect to one set of reference frames would always be seen as travelling backwards in time from another set of reference frames.

2. Philosophy

A general notion of backward causation raises two sets of questions: those concerning conceptual problems and those that relate to empirical or physical matters. Among the first sets of questions that require a satisfactory answer are the following:

(i) *Can metaphysics provide a notion of time that allows that the effect precede its cause?* A proper notion of backward causation requires a static account of time in the sense that there is no objective becoming, no coming into being such that future events exist on the par with present and past events. It means that the future is real, the future does not merely consist of unrealised possibilities or even nothing at all. Ordinarily we may think of the past as a nothing that once was a something. But when asked what makes sentences about the past true or false, we would probably also say that it is the facts of the past that make present sentences about the past either true or false. The fact that I went to the cinema yesterday makes it true today when I say that I went to the cinema yesterday. This view is a realist one with respect to the past. If backward causation is to be conceptually possible it forces us to be realists with respect to the

future. The future must contain facts, events with certain properties, and these facts can make sentences about the future true or false. Such a realist account is provided by static and tenseless theories of time. A static theory holds that the participation of time into the past, the present and the future depends on the perspective we human beings put on the world. The attribution of pastness, presentness and futureness to events is determined by what we take to exist at times earlier than and times later than the time of our experience.

(ii) *Does backward causation mean that a future cause is changing something in the past?* Even most protagonists consider it an unwarranted consequence that the notion, if true, involves the idea that the future is able to change the past. Their answer has therefore usually been that if we have the power to bring something about in the past, what came about really already existed when the past was present. We have to make a distinction between changing the past so it becomes different from what it was and influencing the past so it becomes what it was. A coherent notion of backward causation only requires that the future is able to have an influence on what happens in the past.

(iii) *Can the cause be distinguished from its effect so that the distinction does not depend on a temporal ordering of the events?* The adherents have usually tried to give an account of causation in which the cause and the effect are not seen as regularities between types of events. Various alternative proposals refer to counterfactuals, probabilities, manipulation and intervention, common cause or causal forks. It is, apparently, only a Humean notion of causation that needs the temporal identification of the cause and the effect.

(iv) *Can the bilking argument be challenged in such a way that the mere possibility of intervention does not generate any serious paradoxes?* The force of the bilking argument can, it seems, be weakened in various ways. First, one may hold that it is not a problem for our notion of backward causation that we can in principle intervene in the course of the events. If we actually do so and prevent *A* after *B* has occurred, then of course a particular later *A* (which does not exist) cannot be the cause of a particular earlier *B* (which exists). But in all those cases where nobody actually intervenes, events of the same type as *A* may be the cause of events of the same type as *B*. This is not different from what can happen in some cases of forward causation. Assume that *P* causes *Q* in the relevant circumstances. We may still prevent a particular *P* from happening, but at the same time a particular *Q* may nevertheless occur because in the given circumstances it is caused by another event than *P*. Second, if a later event *A* really causes an earlier one *B*, then it would be impossible to intervene into the cause of the event after *B* has happened and therefore impossible to prevent *A* from happening. If someone tries, she will by all means fail. It may intuitively sound strange as long as we think of backward causation as consisting of something we can control directly by our everyday actions. But if backward causation is a notion that is applicable only to processes that human beings are unable to control in any foreseeable way the notion would not provoke our intuitions so much.

3. Physics

The notion of backward causation raises a very different set of questions that need to be answered before

a physically adequate notion has been developed.

(i) *What, if anything, would in physical terms characterize backward causation?* One has to remember that causality as such is an everyday notion that has no natural application in physics. How we could physically identify backward causal processes depends very much on which feature we take our ordinary notion of causation to apply to a physical process. In physics we may be tempted to associate it with different physical notions of processes. Four suggestions have been put forward: (a) the causal link can be identified with the transference of energy; (b) it can be identified with the conservation of physical quantities like charge, linear and angular momentum; (c) it can be identified with interaction of forces; or (d) it can be identified with the microscopic notion of interaction. It appears with respect to all four suggestions, however, that the involved descriptions are invariant under the time reversal operation.

The most fundamental laws of nature are time reversal invariant in the sense that our physical theories allow description of the fundamental reactions and processes in terms of the time reversed order. Such processes are said to be reversible in time. Maxwell's theory of electromagnetism, for instance, admits two kinds of mathematical solutions for the equations describing the radiation of energy in an electromagnetic field. One is called the *retarded* solution where radiation appears as outgoing concentric waves, the other is named the *advanced* solution according to which radiation appears as incoming concentric waves. Apparently the advanced solution describes the temporal inverse phenomena of the retarded solution so that these two solutions are usually regarded as the time reverse solution of the other. Nevertheless, retarded waves, like the increase of entropy in quasi-closed systems, appear to be *de facto* irreversible although they are described in terms of time invariant laws. Nature seems to prefer certain processes rather than their temporally inversed counterparts in spite of the fact that the laws of nature do not show such a preference. Light, radiation and ripples on a pond always spread outwards from their source rather than inwards just like entropy of a quasi-closed system is always moving from lower to higher states.

3.1 The Wheeler-Feynman Absorber Theory

Why do we not see any advanced waves in nature? Wheeler and Feynman (1945) came up with an answer. If we assume, they said, that radiation from an isolated accelerated charged particle is equally retarded and advanced, that is half retarded and half advanced to be exact, we can explain why it appears to be fully retarded in terms of the influence distant absorbers make on the source. The absorber consists of charged material that reacts with the source field by radiating with half retarded and half advanced waves. It is this half advanced field of the charged particles of the absorber which is added to the half retarded field of the source. The advanced waves of the absorber interfere constructively with the retarded waves of the source, whereas the same waves cancel out the advanced waves of the source in a destructive interference. Thus one of the consequences of Wheeler and Feynman Absorber Theory is the idea that emitters are intrinsically symmetric, another is that there is no intrinsic difference between so-called emitters and so-called absorbers. In other words, if this theory is true we have to conclude that radiation from a source is a time symmetric process but the presence of an absorber makes it asymmetric.

The Wheeler-Feynman theory takes for granted that outgoing, expanding waves are identical with

retarded radiation and incoming, contracting waves with advanced radiation. But is such identification without any problems? Not quite. An example with retarded and advanced emitters illustrates clearly why. Think of a stone being thrown directly into the middle of a circular pond. The ripples move outwards from the point where the stone hits the water (the source) in a coherent, organized wave front and eventually reach the edges (the absorber). Moreover, the source acts earlier than the absorber. What will the inverse process look like? It depends on how we understand such a process, whether or not we consider a case that includes a reversed source and a reversed absorber. (A) If they are included, the edges of the pond will now act as the source and the converging waves will eventually reach the middle of the pond. We may create something like this if we dropped a big ring horizontally into the pond. Inside the ring the waves would move inwards in an organized wave front towards the centre. In this case the source (the drop of the ring) would still act earlier than the absorber (the ripples meeting at the middle of the pond from all sides). (B) But if our understanding of the inverse process does not include an exchange of the source with the absorber and *vice versa*, then the ripples reach the edges of the pond (the absorber) earlier than the stone plunges into the water (the source). This is definitely not a state of affairs we could bring about. Furthermore, if we were to observe such a process, the ripples would seem to move inwards as contracting waves. The problem is that both kinds of inverse processes would seem to appear to us as organized incoming waves but one would be a case of retarded radiation and the other of advanced radiation.

This may not be the only problematic assumption of the Wheeler and Feynman theory. Huw Price (1996) has singled out other problems. Among them is the question of how we may experience the difference between retarded and advanced waves. When Wheeler and Feynman attributed to the source a field of half retarded and half advanced waves, they assumed that the field actually consists of retarded as well as an advanced component. Price objects, however, that there is no measurable difference between the two kinds of waves, and we cannot justify such a distinction by an appeal to the nature of the source because both emitters and absorbers can be associated with retarded as well as advanced waves. Instead he believes that these components are fictitious and that Wheeler and Feynman's formalism merely offer two different descriptions of the same wave. The problem of the asymmetry, as he sees it, has nothing to do with the fact that transmitters are associated with outgoing radiation rather than incoming radiation but that transmitters are centered on organized outgoing wave fronts whereas receivers are not centered on similar organized incoming wave fronts.

3.2 Tachyons

When the discussion of tachyons began to appear in physics in the 1960s, it was soon noticed that such particles according to some frames of reference were associated with negative energies going backwards in time. To understand how, consider the trajectory of the same tachyon in relation of three different reference frames, *S*, *S**, and *S*** in the Minkowski-space. Now assume that *A* is, in relation to *S*, the emission of a tachyon at t_1 and *B* is the absorption of the tachyon at t_2. According to an observer in *S*, *A* will be earlier than *B* and the tachyon will carry positive energy forward in time. Nevertheless it is always possible to select a reference frame *S** in relation to which an observer will see *A* happen simultaneously with *B* and yet another reference frame *S*** in relation to which an observer sees *A* happens at t_2**

whereas *B* happens at t_1**. According to the observer in *S***, *A* will take place later than *B* and the tachyon carries negative energy backwards in time (See Figure 1).

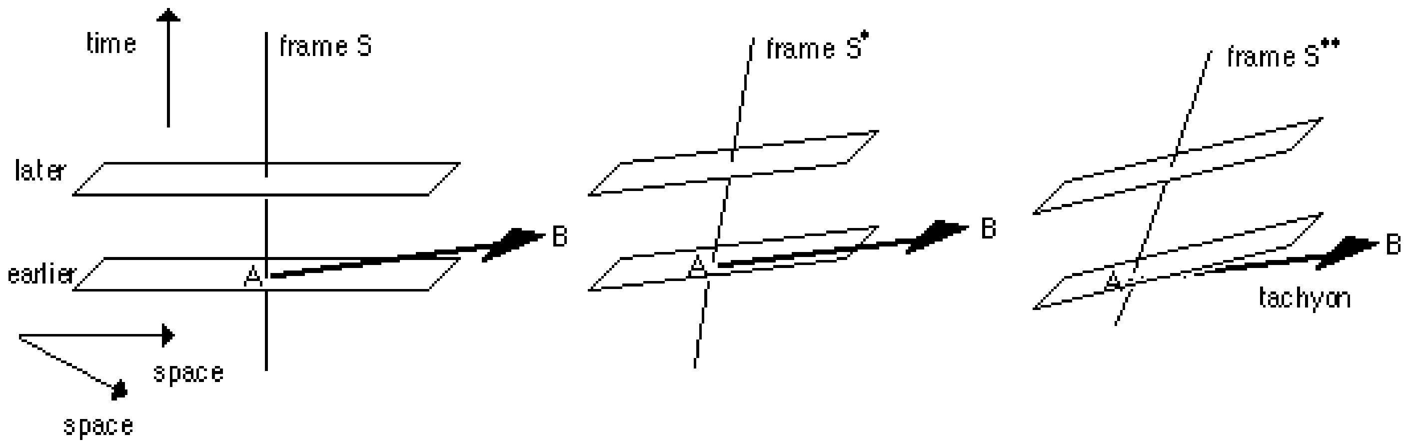

Figure 1

In Figure 1 the planes represent the hypersurfaces of simultaneity. In relation to frame *S* the taychon source is at rest, and a tachyon is emitted at event *A*, with a superluminal but finite velocity. The absorption of the tachyon, event *B*, will accordingly occur later than *A* in relation to the observer in *S*, and the arrow of trajectory is for that reason pointing into the future above the hypersurface passing through *A* and standing perpendicular to the world-line of the source. But neither with respect to the frame *S** nor *S*** is the tachyon source at rest and the hypersurfaces are therefore tilted in relation to the arrow of trajectory. An observer in *S** observes the tachyon to have infinite speed, and therefore the hypersurface is tilted so much that it coincides with the arrow. The observer in *S*** is moving so fast with respect to the tachyon source that the hypersurface becomes titled so much that the arrow points into the past below the hypersurface.

E. Recami (1978) tried to avoid the idea that tachyons could move backwards in time by introducing the so-called reinterpretation principle according to which all negative energy tachyons should be interpreted as if they have positive energy and move forward in time. This would mean that the causal order of tachyons should not be regarded objective since both *A* and *B* sometimes denoted the emission and sometimes the absorption depending on the frame of reference. There are, however, good reasons to believe that this suggestion does not solve the problems it was intended to (Faye, 1981/1989).

3.3 Quantum Mechanics

Other physical candidates for backward causation can be founded in the physics literature. Richard Feynman once came up with the idea that the electron could go backwards in time as a possible interpretation of the positron (Feynman, 1949). In fact he imagined the possibility that perhaps there were only one electron in the world zig-zaging back and forth in time. An electron moving backwards in time would carry negative energy whereas it would with respect to our ordinary time sense have positive charge and positive energy. But few consider this as a viable interpretation today (Earman, 1967, 1976).

More recently the Bell type experiments have by some been interpreted as if quantum events could be connected in such a way that the past light cone might be accessible under non-local interaction; not only in the sense of action at a distance but as backward causation. Costa de Beauregard (1977, 1979), for instance, has suggested that when a system of two photons in a singlet state is measured by two observers in two regions separated by a space-like distance, then it is precisely the act of observation that produces the past of the measuring process in the sense that it influences the source that emitted the two photons. de Beauregard's idea is that the element of reality being revealed in the formulation of the EPR paradox is real only because it was created by actually performed acts of observation that was propagated backwards in time with one of the two correlated quantum objects from the measuring device to the source of the photons. Several other philosophers and physicists have come forward with similar ideas. The basic assumption behind all of them is that in the micro-world we find only causal symmetry and this fact together with proper boundary conditions can be used to give an explanation of outcomes that seem otherwise paradoxical. Such quantum correlation experiments can, however, be interpreted in many other ways.

3.4 Two alternatives

These alleged examples of backward causation have one thing in common. They are all based on the idea that fundamental physical processes are by themselves symmetric in nature. Our ordinary notion of causation does not track any nomological feature of the world. What counts as the cause and the effect depends on the observer's projection of his or her temporal sense onto the world. So it is still an open question how a coherent notion of backward causation can fit into this general understanding of nature. The question we therefore have to answer is the following:

(ii) *How can we distinguish between forward causation and backward causation if all basic physical processes are time symmetric according to our description of nature?* Two very different reactions to this problem seem possible.

3.4.1 Boundary Conditions

One proposal is to say that if we came across reversed cases of *de facto* irreversible processes, such as running a film backwards in which the cream converged in a coffee cup, such cases should be interpreted as examples of backward causation (Price, 1996). The point is here to argue that it is the absence of the right initial or boundary conditions that makes backward causation so rare or nearly empirically impossible. This interpretation is based on three basic assumptions: (i) there is no objective asymmetry in the world, causal processes are intrinsically symmetric in nature, or causation is bidirectional, and therefore the fundamental processes of the micro-world are temporally symmetric; (ii) causal asymmetry is subjective in the sense that any attribution of an asymmetry between cause and effect depends on our use of counterfactuals and our own temporal orientation; (iii) backward causation, or advanced action, is nonetheless possible because sometimes the correlation of certain past events depends on the existence of causally symmetric processes and some future boundary conditions. For instance, advanced actions in electrodynamics require that the existence of transmitters in the future are centered on organized incoming wave fronts; and advanced actions in quantum mechanics require that their present states are in part

determined by the future conditions (measurements) they are to encounter. This feature is then taken to explain Bell's results in quantum mechanics.

A simple consideration seems to support this interpretation. Think of a particle travelling between two boxes. The normal observer and the counter-observer who has an inverse time sense will describe the exchange in conflicting terms. To the normal observer Box 1, say, will be considered as the emitter because it loses energy before anything in Box 2 happens. Therefore, Box 2 will be considered as the receiver since it gains energy at a later time. So in relation to the normal observer, the particle travels from Box 1 to Box 2. The counter-observer, however, sees the situation with opposite eyes. In relation to him, Box 2 loses energy and not until thereafter does Box 1 gain a similar amount of energy. Accordingly, in relation to the counter-observer, the particle moves from Box 2 to Box 1. In other words whether a box is considered to be an emitter or a receiver depends on the observer's time sense.

3.4.2 Nomic conditions

The other proposal denies that basic physical processes are time symmetric and argues, in contrast, that the causal asymmetry is objective and therefore that there exists an intrinsic difference between the cause and the effect of all physical processes. Hence backward causation should not be considered as a notion about boundary conditions but as a notion concerned with processes that nomically distinguish themselves from forward causal processes. Thus, if there are processes in the world that might be seen as a manifestation of backward causation, these are not to be depicted by a description that leaves them to be time reversed cases of ordinary forward causal processes (Faye, 1981/1989, 1997, 2002). This alternative interpretation rests on a basic claim and four assumptions.

The fundamental claim is that for any observer it is possible to identify experimentally the cause and the effect so that these remain the same even in relation to counter-observers, i.e. observers having the opposite time sense of ours. In support of this claim consider the following thought experiment. Two boxes, each having a shutter, are facing each other. Assume, ex hypothesis, that Box 1 is the particle source and Box 2 is the particle receiver. The question is how a normal observer and a counter-observer can come to agreement that particles move from Box 1 to Box 2. The answer can be found through a series of manipulations with the shutters, I would say. There are four possible combinations of the two shutters: open-open, close-close, open-close, close-open. Let us call any change of energy in Box 1, regardless of whether it emits or receives a particle, *A* and, similarly, any change of energy in Box 2 *B*. Whether *A* or *B* stand for a gain or a loss of energy can be determined by weighing the two boxes. (i) In case both boxes are closed, no particle will leave Box 1 and no particle is received by Box 2, thus no gain or loss of energy occurs, and both the normal observer and the counter-observer see a situation of not-*A*, not-*B*. (ii) In case both boxes are open a particle leaves Box 1 and is received by Box 2. Again this can be observed by measuring the change of energy in the two boxes. Thus the observers will see a situation of both *A* and *B*. (iii) In case Box 1 is closed and Box 2 is open, they will observe no change of energy in Box 1 (because it is closed) and, since no particle is leaving Box 1, no particle will reach Box 2 although its shutter is open. Hence the observers measure no energy change in this box. Thus they see not-*A* and not-*B*. (iv) Finally, if Box 1 is open and Box 2 is closed, a particle leaves Box 1, but none is received by Box 2. In other words, there is a loss or a gain of energy in Box 1, but no loss or gain of energy in Box 2.

So the observers see *A* and not-*B*. The upshot of this toy experiment is that the normal observer as well as the counter-observer experience two *A*s but only one *B*, and one not-*A* but two not-*B*s; therefore both will agree that the particles move from Box 1 to Box 2.

This means that what a normal observer identifies as a forward causal process will be regarded as a backward causal process in relation to the counter-observer in the sense that the very same event acting as a past cause for the normal observer will act as a future cause for the counter-observer. This indicates, too, that in relation to a normal observer forward causation and backward causation cannot be regarded as two different manifestations of nomologically reversible (but *de facto* irreversible) processes since both manifestations - the common process and the very improbable reversed process - would develop forward in time. If this claim is true, it implies that the description of physical processes should reflect such an intrinsic asymmetry in a way that the nomic description varies according to whether the process in question goes forward or backwards in time. Moreover, we must also be able to distinguish theoretically (and not only experimentally) between the normal observer's report and the counter-observer's report of the same process by a separate convention in respect to whether the process is forward moving or backward moving. What we want is a characterization of every physical process so that the invariance of cause and effect corresponds to *nomological* irreversibility.

In order to establish a nomic, intrinsic distinction between forward causal processes and backward causal processes one has to take departure in four assumptions. (i) Process *tokens* and process *types* are distinct in the sense that only process types are reversible, process tokens are not. (ii) A normal observer will describe causal processes propagating forward in time *in terms of positive mass and positive energy states pointing into her future* whereas she will describe the same tokens *in terms of negative mass and energy states pointing into her past*. This reflects two possible solutions of the four-momentum vector in the theory of relativity. (iii)Thus, one must distinguish between a *passive* time reversal operation and an *active* time reversal operation. The passive transformation is applied to the same process token by *describing* it in terms of opposite coordinates and opposite energy states. The active transformation, in contrast, brings about another token of the same process type in virtue of some physical translation or rotation of the system itself, both tokens having the same energy sign pointing in the same direction of time. (iv) The description in terms of positive mass and the possitive energy flow corresponds to the intrinsic order of the propagation.

Now, let us try to apply the nomic interpretation to the above consideration concerning the exchange of a particle between two boxes. In relation to the normal observer who describes the particle in terms of its *positive energy component*, it travels from Box 1 to Box 2 because Box 1 looses energy at an earlier time and Box 2 gains energy at a later time. The same situation is by the counter-observer described in terms of the particle's *negative energy component* as a situation where something happens in Box 2 before it happens in Box 1. In relation to the counter-observer, Box 2 would not, as the boundary interpretation suggests, loose energy. On the contrary, Box 2 would seem to gain energy, but the counter-observer would describe the particle as a series of negative energy states reaching into his future supposing the particle to be moving from Box 2 to Box 1 carrying negative energy. But, as we have just argued, the particle really moves from Box 1 to Box 2, from the counter-observer's future into his past carrying positive energy.

Consequently, the nomic interpretation holds that in relation to our normal time sense the causal direction of ordinary processes is identical with that of their reversed processes. In other words, take two tokens of a nomologically reversible process type, say *A* and *B*, and let *B* be the actively time reversed process of *A*, then this interpretation claims that *A* and *B* causally develop in the same direction of time. So, according to this view, neither incoming, contracting electromagnetic waves nor the decrease of entropy would count as examples of backward causation as long as such processes involve ordinary types of matter, i.e., matter that possesses positive mass and/or energy pointing, in relation to our normal time sense, towards the future. The notion of backward causation should instead be applied to matter of a different type, particles that appear to have, according to usual conventions, *negative mass and/or energy pointing, in relation to our normal time sense, towards the future but positive mass and/or energy pointing towards the past*. Such advanced matter, if it exists, should be distinguished from both ordinary retarded matter as well as tachyons by always being described with respect to our time sense in terms of negative mass and energy stretching forward in time. A consequence is that a world in which advanced matter exists together with retarded matter, and where advanced matter is able to interact directly with the same amount of retarded matter, both would, in case they actually did interact, annihilate without leaving any trace of energy.

How and whether the notion of backward causation has a role to play in physics has yet to be seen. But as long as no common agreement exists among philosophers and physicists about what in the physical description of the world corresponds to our everyday notion of causation, it would still be a matter of theoretical dispute what counts as empirical examples of backward causation.

Being and Becoming in Modern Physics

Does time flow or lapse or pass? Are the future or the past as real as the present? These metaphysical questions have been debated for more than two millennia, with no resolution in sight. Modern physics provides us, however, with tools that enable us to sharpen these old questions and generate new arguments. Does the special theory of relativity, for example, show that there is no passage or that the future is as real as the present? The focus of this entry will be these new questions and arguments.

---

1. Introduction

Around 500 B. C. Heraclitus wrote the following:

> Everything flows and nothing abides; everything gives way and nothing stays fixed.
>
> You cannot step twice into the same river, for other waters and yet others, go flowing on.
>
> Time is a child, moving counters in a game; the royal power is a child's.[1]

Transience is basic, and the present is primary. Those things which exist now do not abide. They slip into

the past and non-existence, devoured by time, as all experience attests.

A generation or so later we have a classic statement of the opposing view by Parmenides:

> There remains, then, but one word by which to express the [true] road: Is. And on this road there are many signs that What Is has no beginning and never will be destroyed: it is whole, still, and without end. It neither was nor will be, it simply is—now, altogether, one, continuous…

Permanence is basic. No things come to be or, slipping into the past, cease to be. Past, present, and future are distinctions not marked in the static Is. Time and becoming are at best secondary, at worst illusory, as our understanding of the world confirms.

Turn now to modern times and to a paragraph in Rudolf Carnap's intellectual autobiography (Carnap 1963, pp. 37-38):

> Once Einstein said that the problem of the Now worried him seriously. He explained that the experience of the Now means something special for man, something essentially different from the past and the future, but that this important difference does not and cannot occur within physics. That this experience cannot be grasped by science seemed to him a matter of painful but inevitable resignation. I remarked that all that occurs objectively can be described in science; on the one hand the temporal sequence of events is described in physics; and, on the other hand, the peculiarities of man's experiences with respect to time, including his different attitude towards past, present, and future, can be described and (in principle) explained in psychology. But Einstein thought that these scientific descriptions cannot possibly satisfy our human needs; that there is something essential about the Now which is just outside the realm of science. We both agreed that this was not a question of a defect for which science could be blamed, as Bergson thought. I did not wish to press the point, because I wanted primarily to understand his personal attitude to the problem rather than to clarify the theoretical situation. But I definitely had the impression that Einstein's thinking on this point involved a lack of distinction between experience and knowledge. Since science in principle can say all that can be said, there is no unanswerable question left. But though there is no theoretical question left, there is still the common human emotional experience, which is sometimes disturbing for special psychological reasons.

This difference as expressed here between Einstein and Carnap (that is, between the Heraclitean and Parmenidean attitude towards time and change) is the subject of this article, which will use modern physics--especially modern spacetime theory--as a set of lenses through which it is hoped the riddles of time will come into sharper focus. There are many ways, however, to approach these questions. Early in the twentieth century, Anglo-American philosophy turned to consideration of language as way to clarify philosophical disputes. Philosophers of time debated the relative primacy of tensed language (concerning

the notions of present, past, and future) or tenseless language (concerning the relations of simultaneity and temporal precedence). Our considerations of physics will generally, though not completely, skirt linguistic disputes. The reader interested in following these debates can find a sophisticated review and discussion in Tooley (1999).

Other philosophers have been influenced by analogies between time and modality. The reader interested in this way of thinking about time should consult the article Temporal Logic. The present article will focus on time in physics and the relations between time and space. Other philosophical approaches focus on the primacy of experience in our understanding of time. The reader interested in these approaches may wish to consult The Experience and Perception of Time.

2. Newtonian Spacetime

Modern physical theories are often formulated in a language that permits one to express a variety of different views with respect to time and its relation to space. One can, for example, formulate the basic ideas of classical (that is, Newtonian) physics, the special theory of relativity, and the general theory of relativity in this language. For a brief introduction to the spacetime view, see Section 1 ("Modern Spacetime Theories: A Beginner's Guide") of John Norton's entry on The Hole Argument in this Encyclopedia. For more detail with minimal technical demands the reader should see the first four chapters of Geroch (1978) or (more demanding) chapter 2 of Friedman (1983).

For our purposes, the defining feature of a manifold that is a Newtonian spacetime is that the temporal interval between any two points or events in the spacetime, *p* and *q*, is a well-defined quantity. This quantity is well-defined in that it does not depend upon point of view, reference frame, coordinate system or "observer". This quantity, then, is *absolute* in the sense of being frame- or observer-independent. (In the special theory of relativity the temporal interval between two distinct spacetime points fails to be absolute in this sense.)

If the temporal interval between two events is 0, then we say that the two events are *simultaneous*. This relation of (absolute) simultaneity is an equivalence relation (That is, it is reflexive, symmetric, and transitive.) that slices (partitions or foliates) the spacetime or manifold into mutually exclusive and exhaustive planes of simultaneity. These planes of simultaneity can then be completely ordered by the relation 'is earlier than' or its converse 'is later than'.

2.1 Presentism, Possibilism, Eternalism

The geometrical structure of Newtonian spacetime reflects the way we ordinarily think about time and is the proper backdrop for introducing the three major rival metaphysical views of time, as illustrated below:

Figure 1

Figure 1. Three Metaphysics of Time

The first view, represented on the left, is the ontologically austere view called *presentism*, the view that only the present exists. The past has been but is no longer, while the future will come to be but is not yet. Note that it is the convention of these diagrams that one spatial dimension is suppressed. The present is actually a three dimensional global slice of the spacetime. Moreover, the illustration necessarily represents the spatial extent of the present as finite and may suggest that time also has a beginning and/or end. These views are, however, merely artifacts of the representation and not integral to presentism, possibilism, or eternalism. The diagram illustrating presentism also has four arrows pointing up (conventionally, towards the future) attached to the plane representing the present. These arrows are meant to indicate something that is integral to presentism, the idea that the present (and hence the existent) constantly shifts or changes. These arrows represent, then, the dynamic aspect of time called *temporal becoming* or *passage.* The deepest problem in the metaphysics of time is how to understand passage or becoming and its relation to existence.

In contrast to the radical Heraclitean view of presentism, the Parmenidean eternalist picture on the far right lacks these arrows and indicates that there is no more special about the temporal present (the *now*) than the spatial present (the *here*). Future and past events at a place, on this view, are no more or less real than distant events at a time. The *now* like the *here* is a function of one's perspective, one's position in the spacetime, and these positions are indicated by the line in the spacetime representing the history of spacetime locations of a particular object or person. Such a line is often called a *world line.*

The middle view, possibilism, is indeed an intermediate view. It is a passage view, but it is less ontologically sparse than presentism. While on this view the future is still merely possible rather than actual (hence its name), the past has become and is fully actual. If one thinks of the future as a branching structure of alternative possibilities (as the result, for instance, of free human choices or indeterministic quantum measurements), then one can think of the past and present as the trunk of that tree, growing as possibilities become actual in the present.

Possibilism seems to capture much of the way we think about time and being. While the sparse symmetry of presentism is attractive, there are many deep asymmetries concerning past and future that it fails to reflect. I can easily ascertain, for instance, yesterday's closing number for the Dow Jones Industrial Average, but by no efforts, however great, can I now ascertain tomorrow's close. And it seems as if my actions (or certain sorts of quantum measurements) can actualize some future possibilities as opposed to others, whereas past actions (or the results of past quantum measurements) seem no longer to admit of alternatives. Even if one allows for the possibility of retrocausation, for the possibility of an effect preceding its cause in time, it is generally held that a present cause can not change or alter the past. It would merely make the past what it was. (See the entry Backwards Causation for further consideration of this topic.)

Eternalism too, *prima facie*, would seem to have trouble accounting for the asymmetries built into

possibilism, in addition to its implausible denial of passage. But the first topic to which we shall turn is an argument, prominent in twentieth century philosophy of time, that passage or becoming is a self-contradictory idea. If the argument is correct, then neither presentism nor possibilism can be correct metaphysical views of time and being.

2.2 McTaggart's Argument

At the beginning of the 20th century, J. M. E. McTaggart (1908) presented an argument which purported to prove that time is unreal. According to McTaggart (1927, pp. 9-10):

> Positions in time, as time appears to us prima facie, are distinguished in two ways. Each position is Earlier than some and Later than some of the other positions… . In the second place, each position is either Past, Present, or Future. The distinctions of the former class are permanent, while those of the latter are not. If *M* is ever earlier than *N*, it is always earlier, But an event, which is now present, was future, and will be past.

The first structure of "positions in time," McTaggart called *the B-series.* I will assume that McTaggart intended the B-series to coincide with the classical spacetime structure described above. McTaggart noted that there was something static or "permanent" about the B-series. If, for example, event e_1 is earlier than event e_2 at some time or other, then it is earlier than e_2 at all times.

The dynamic element of time must be represented, in McTaggart's view, by the series of properties of pastness, presentness, and futurity, which (in contrast to the static B-series) are constantly changing. A given event becomes less future, becomes present, and then becomes increasingly past. This latter ever-shifting series McTaggart called *the A-series.*

While there are many obscurities in McTaggart's writing, it seems clear that the argument intended to prove that time is unreal runs along the following lines:

(1) there can be no time unless it has a dynamic element (that is, on his view, unless there is an A-series),

(2) there can be no A-series, because the supposition that there is an A-series leads to contradiction.

The contradiction alleged by McTaggart is that:

(A_1) every event must have many, if not all, the A-properties (or A-determinations, as they are sometimes called) whereas,

(A_2) since the A-properties are mutually exclusive, no event can have more than one of them.

Near the end of career in which he spent much time and effort in thinking about McTaggart's argument, C. D. Broad (1959, p. 765) wrote:

> I felt from the first, and still feel, that the difficulty which arises is (a) embarrassing enough prima facie to demand the serious attention of anyone who philosophises about time, and (b) almost certainly due to some purely linguistic source (common, and perhaps peculiar, to the Indo-European verb-system), which it ought to be possible to indicate and make harmless.

Broad's claim (a) was vindicated by the fact that McTaggart's argument has received serious attention from most subsequent philosophers who pondered the metaphysics of time. Much of this debate concerns the relative relations of the two series. Is the A-series fundamental and the B-series derived from it, or vice versa, or does, perhaps, one series supervene upon the other? In the formal mode, the questions become whether the B-series may somehow be reduced to, may be defined in terms of, the A-series (or vice versa). These debates concern mainly language rather than physics and will not be considered here.[2]

What emerges from the McTaggart literature that is relevant to this discussion is, first of all, a tendency to identify the existence of passage or temporal becoming with the existence of the A-series (that is, to think of becoming as events changing their properties of pastness, presentness or nowness, and futurity) and hence the tendency for debates about the existence of passage to focus on the merits or incoherence of the A-series rather than examining alternative accounts of becoming. (But Cf. Fitzgerald, 1985)

There is a tendency amongst those philosophers who take modern physics seriously to be sceptical of entities like constantly shifting temporal properties of events, since such properties seem to play no role in modern physical theory. One view, defended by Paul Horwich (1987, Chapter 2) and Huw Mellor(1981, 1998), is that even though McTaggart showed that passage (that is, the A-series) is impossible, the B-series (that is, static classical spacetime structure) suffices for time.

Before we expand on this theme, though, first a few words about Broad's (b), his suspicion that there is some peculiarity of our language(s) that creates or at least reinforces the credibility of McTaggart's anti-passage argument. Broad suspected that there was a subtle ambiguity in the copula ‘is’ between tensed and tenseless uses, between the uses in, for instance:

> It is raining

and

> Seven is prime,

the former sentence containing a tensed and the latter sentence a non-tensed or tenseless copula. It has

been further suggested (Sellars 1962) that one might understand a non-tensed copula (indicated by 'be' rather than 'is') after the following fashion

> *S* be *F* at *t* iff (*S* was *F* at *t* or *S* is *F* at *t* or *S* will be *F* at *t*),

where the verbs to the right of the 'iff' (a logician's abbreviation for 'if and only if') are usual tensed verbs.

Alternatively, one might think of a tenseless copula as the usual copula stripped of temporal information (Quine, 1960, p. 170, Mellor 1981, 1998, Chapter 7), just as the usual copula carries no spatial information. If we indicate this tenseless copula by writing 'BE' instead of 'is,' we can say that 'It BE windy in Chicago' carries information about the place but not the time of the wind, just as 'It BE windy at t' tells us about its time but not its place.

These distinctions will prove helpful in the subsequent discussion of being in modern physics. For the moment, one might note that Broad could argue that McTaggart's (A_1) seems plausible if the copula is understood in some tenseless fashion, whereas (A_2) is plausible if the copula is tensed. If, however, the copula is not univocal in (A_1) and (A_2), then there is no contradiction involved in accepting both. (Savitt, 2001)

2.3 How (and How Not) To Think About Passage

If McTaggart's argument that passage is conceptually absurd or self-contradictory fails, philosophers mindful of modern physics are still left with Einstein's concern that passage and the now, while deeply embedded in human experience, seem to find no place in physics. One may agree with Carnap that "all that occurs objectively can be described in science" and then argue that passage reflects something perspectival or subjective and so is implicit in the physics or rightly omitted by it.

The most popular version of this view holds that *now* is a token-reflexive or indexical term, like *here* (Smart 1963, chapter VII; Mellor 1981, 1998). Physics is not felt to be incomplete because it fails to treat *hereness.* Why should its indifference to *nowness* be of any greater concern?

Early proponents of this view often claimed that '*S* is now *F*' meant '*S*'s being *F* is simultaneous with this utterance,' a quite implausible claim. A more sophisticated version of the view is that the truth-conditions of sentences like '*S* is now *F*' can be given solely in terms of the (tenseless) facts that exist or events that occur at the time of the utterance or inscription of the given sentence. It should be obvious how to extend the position to treat *past* and *future* in a similar fashion.

Smart claimed that excessive attention to the tensed notions of *now, past,* and *future* serve to project a "sort of anthropocentric idea on the universe at large."(1963, 132) But even if the tensed temporal locutions are anthropocentric and do locate *us* in the universe, it may still be asked whether these

temporal locations are in a static structure, “a four-dimensional continuum of spacetime entities,” (132) or in an unfolding or dynamic universe. Smart dismisses this latter view because, in his view, it involves the obscure or mistaken idea that events “become” or “come into existence.” Becoming and passage are mistakes, and harmful ones at that. Smart writes: “Our notion of time as flowing, the transitory aspect of time as Broad has called it, is an illusion which prevents us seeing the world as it really is.“ (132)

It will be useful to untangle a couple of ideas that are confounded in these quotes from Smart, with the help of some arguments of (mostly) Broad's (1938, section 1.22 of Chapter 35). First is the idea that time “flows” or, more generally, that passage is somehow to be thought of as like motion. Perhaps time itself somehow moves. Or perhaps, as Broad wrote in a famous sentence, “[t]he characteristic of presentness is … supposed to move along this series of event-particles, in the direction from earlier to later, as the light from a policeman's bullseye [flashlight] might move along a row of palings.”

Motion is one sort of change, change of spatial position with respect to time. The motion of time, then, must be change of time with respect to … What? If the answer, by analogy with motion, is “time”, one might be rightly puzzled as to how time (or anything else, for that matter) can change *with respect to itself.* Furthermore, if it is just time again, then the ratio of these two quantities expressing the rate of change is a pure or dimensionless number if the dimensions of the quantities in this ratio cancel. (See Price 1996, p. 13.) A pure number is not a rate of change, although it may represent various rates of change (for instance, 30 meters/second or 30 miles/hour). As Price remarks, “We might just as well say that the ratio of the circumference of a circle to its diameter flows at π seconds per second!”

If (in order to avoid this absurdity) the time in the denominator of the ratio expressing the rate of time's motion is held to be a different temporal dimension from the one in the numerator, then for it to be a genuine time there will have to be passage in it, requiring yet a third temporal dimension. One can see that we are at the beginning of an infinite regress, unless the third temporal dimension is identified with the first (as in Schlesinger 1980, Chapter II), leaving us in the uncomfortable position of having two temporal dimensions. It seems at best heroic, at worst hopeless, to try to understand passage as a kind of motion.

Broad also thought that trying to explain or represent passage in terms of qualitative change was “doomed to failure.” A thing or substance, *S*, can change in terms of a quality or property if property P_1 and property P_2 are determinates under a given determinable and *S* is P_1 at t_1 but P_2 at t_2. The passage of time, then, is to be thought of as an event's having (say) the property of presentness and then immediately losing that property but gaining (and losing in turn) a long and possibly endless series of properties of the increasing degrees of pastness.

In order for a thing to change it must evidently persist at least from t_1 to t_2, but the events usually supposed in discussions of passage are instantaneous events, which have no duration at all. They can not undergo qualitative change. It is sometimes argued that the properties that make up the A-series (and so change of which represents passage) are special properties, which even instantaneous events can gain and lose, but this is special pleading. As noted above, physics has so far no need of such special properties

and such special change and so is unlikely to be sympathetic to this special pleading.

Finally, Broad notes that (assuming one wishes to think of passage as like qualitative change) the acquisition and loss of (say) presentness by an event would itself be an event, a second-order event, in the history of a first-order event. Since the first-order events are, by hypothesis, durationless, it is tempting to suppose that this history takes place in a second temporal dimension. We find ourselves again launched on what looks to be an infinite regress of temporal dimensions.

These are strong arguments against two perennially tempting ways to construe temporal becoming--as like motion or qualitative change. They are strong arguments against the existence of temporal becoming if there is no other way to understand it. Broad thought, however, that he had a third way. Having pointed out the superficial grammatical similarity between '*E* became louder' and '*E* became present', Broad said that our understanding of these two kinds of assertions need not be dictated by it. He wrote (1938, p. 280-1):

> Again, any subject of which we can significantly say that it "became louder" must be a more or less prolonged noise-process, which divides into an earlier phase of less loudness adjoined to a later phase of greater loudness. But a literally *instantaneous* event-particle can significantly be said to "become present"; and, indeed, in the strict sense of "present" *only* instantaneous event-particles can be said to "become present". To "become present" is, in fact, just to "become", in an absolute sense; i.e., to "come to pass" in the Biblical phraseology, or, most simply, to "happen". Sentences like "This water became hot" or "This noise became louder" record facts of *qualitative change.* Sentences like "This event became present" record facts of *absolute becoming.*

The terminology may be pretentious, but the idea is simple. Absolute becoming is just the happening of events. The *raison d'être*, the very being or existence of events, is in their happening (at some place and time). If one is willing to embrace this category of entity at all, then one has the tools for a minimalist understanding of passage. Given the geometric richness of Newtonian spacetime, we can say that some events occur at the same time and so form a class of simultaneous events. If these classes can be, somehow, ordered, then we can say that some events occur before or after others. The passage of time is just the successive happening of (simultaneity sets of) events. It may be this picture of passage that the great logician Kurt Gödel had in mind when he wrote (1949, p. 558): "The existence of an objective lapse of time … means (or, at least, is equivalent to the fact) that reality consists of an infinity of layers of 'now' which come into existence successively."

There is an ambiguity in this last quote, however, that we must note. Did Gödel think that the layers of now come into existence (as what is to be becomes what is now) and then immediately cease to exist (as what is now becomes what once was), which is the presentist metaphysics of time? Or did he think that the layers of now come into existence and forever stay in existence, as the possibilist picture maintains? If one's basic ontology consists of the sort of events characterized above and often invoked in discussions of time, (idealized) instantaneous happenings, then the presentist picture seems inevitable.

The metaphysics of time is, however, one of the cross-roads of philosphy where issues intersect. If one thinks of a basic ontology consisting not of events but of substances or continuants, then one is apt to wonder what it is that makes sentences marking episodes in the histories of such substances--sentences like ‘*S* is Φ at *t*’--true. One frequent suggestion is that the “truth-makers” of such sentences are facts, the fact that at *t*, *S is* Φ. Then one might further note that in the current year, 2001, we can say:

1. It is a fact that Mount St. Helens erupted in Washington in 1980.
2. It is a fact that Jean Chretien is now Prime Minister of Canada.
3. It is a fact that there will be an eclipse of the sun in the Eastern United States in 2017.

These facts, when compared to evanescent events, seem to have great stability, the first one lasting (since it *is* a fact …) at least from 1980 till the present. The third one is, however, a special sort of fact, clearly not dependent on human will or choice and almost certainly not dependent upon any quantum measurements either. Future facts that do depend upon human choice or quantum measurement, should they be facts now, would seem to constrain human choice or quantum measurement in ways that many philosophers find undesirable. It is easy to convince oneself, then, that future facts of those two sorts can not really be part of the existing. Perhaps, then, facts like fact 3 above can be argued away as well. The result of this (lightly sketched) train of thought is, of course, the possibilist picture of time.

It seems unlikely that a simple argument will decide between these two metaphysical pictures of time, presentism and possiblism. Showing that McTaggart's argument is flawed, because it relies on an ambiguity in the copula ‘is’, and that there is a way to construe passage that side-steps the traditional objections, moreover, does not show that eternalism is false but only that it is optional. In Newtonian spacetime it may appear implausible, but it may fare better when we turn to Minkowski spacetime.

3. The Special Theory of Relativity

The Special Theory of Relativity (Einstein, 1905) was presented as a geometric theory of spacetime in Minkowski (1908).[3] For our purposes, the key change from Newtonian spacetime to Minkowski spacetime is that in the latter it is no longer the case that the temporal interval between any two points or events in the spacetime, *p* and *q*, is a well-defined quantity. In fact, the temporal interval between two points in the spacetime (and hence the simultaneity of two points in the spacetime) is not defined at all until a coordinate system or frame of reference (with some arbitrarily chosen spacetime point as origin of the frame) is chosen. A peculiar feature of special relativity (as opposed Newtonian physics) is that each coordinate system or frame of reference defined by an “observer” passing through the chosen origin and moving with some constant non-zero speed that is less than the speed of light (as measured in the first frame) picks out a *distinct* set of points as simultaneous with the origin. This feature of special relativity is called *the relativity of simultaneity*.

The relativity of simultaneity is a consequence of the even more startling assumption that each of these “observers”, no matter at what speed or in which direction they or the source of the light are moving (as

long as neither the speed nor the directions change), must come to the same result (conventionally indicated as *c*) when they measure the speed of light. We will not attempt to justify the assumption of the constancy of the speed of light here, though many standard texts present the empirical and theoretical background the led to it. Nor is it obvious that this assumption leads to the relativity of simultaneity, though one of the joys of even elementary presentations of the subject is that this *prima facie* astonishing connection can be convincingly demonstrated to persistent non-specialists.

A second assumption typically made in presentations of the special theory is *the Principle of Relativity:* All inertial frames of reference are completely equivalent for the formulation of the laws of physics.[4]

A glance back at Figure 1 reminds us that presentism and possibilism suppose that one plane of simultaneity is uniquely metaphysically important. In the former view, it represents all that exists. In the latter view, it is the locus of becoming, the dividing line between the merely possible future and the actual past-plus-present. The special theory of relativity tells us that there is an infinity of planes of simultaneity passing through any given spacetime point and that no physical test can distinguish one from amongst the lot. What was metaphysically distinguished is now physically indistinguishable. Assuming that we humans are complex physical systems, then we have no way to distinguish *the* present from amongst the multitude of presents.

An enthusiast could make much of this fact. For instance, the mathematician (and science fiction writer) Rudy Rucker wrote (1984, p. 149):

> As it turns out, it is actually *impossible* to find any objective and universally acceptable definition of "all of space, taken at this instant."" This follows … from Einstein's special theory of relativity. The idea of the block universe is, thus, more than an attractive metaphysical theory. It is a well-established scientific fact.

On the other hand, the distinguished philosopher and logician Arthur Prior thought that the above conclusion showed that special relativity is an incomplete view of reality (Prior, 1970):[5]

> One possible reaction to this situation, which to my mind is perfectly respectable though it isn't very fashionable, is to insist that all that physics has shown to be true or likely is that in some cases we can never *know*, we can never *physically find out*, whether something is actually happening or merely has happened or will happen.

We shall look at more nuanced reactions to the relativity of simultaneity below, but first it will be useful to introduce an argument that plays somewhat the same role in Minkowski spacetime as McTaggart's argument did in Newtonian spacetime. Versions of the argument are endorsed in papers by the physicist Cornellis Rietdijk (1966, 1976) and the philosopher Hilary Putnam (1967), but the presentation here will be based on an example found in Roger Penrose's book, *The Emperor's New Mind*.

Imagine that the Andromeda galaxy, which is about two million light years or 2×10^{19} kilometers from

Earth, is at rest with respect to Earth. On Earth two friends walk past each other, Alice walking along the Earth-Andromeda line towards Andromeda, Bob walking along that line but away from Andromeda. Each is walking at a comfortable pace, say 4 km/hour. One can calculate that their planes (or spaces) of simultaneity at the instant at which they pass each other on Earth (Call the event of their meeting **O**) intersect the history or *world line* of Andromeda about 5 ¾ days apart. (Call these two events **A** and **B**, respectively. We are idealizing Andromeda as a point, for the purpose of this example.) Imagine, finally, that during this 5 ¾ day period between **B** and **A** a momentous thing happens. The Andromedeans launch a space fleet aimed at invading Earth.

Figure 2. The Andromedean Invasion

The launch of the invading fleet is prior to **A** and so *in some sense* in Alice's past. But since the launch is after **B**, it is in that same sense in Bob's future. Penrose comments:

> Two people pass each other on the street; and according to one of the two people, an Andromedean space fleet has already set off on its journey, while to the other, the decision as to whether or not the journey will actually take place has not yet been made. How can there still be some uncertainty as to the outcome of that decision? If to *either* person the decision has already been made, then surely there *cannot* be any uncertainty. The launching of the space fleet is an inevitability. (p. 303)

This is an odd situation indeed. An event in Bob's future seems in some way to become fixed or inevitable by being in Alice's past. But that is not the end of the oddness here. Imagine that at point **A** (where Alice's plane of simultaneity intersects the world line of Andromeda) there is an Andromedean, Carol, who is walking directly towards Earth at about 4 km/hour. Then Carol's plane of simultaneity intersects Earth at some point **C** which is about 11 ½ days after **O**, the meeting of Alice and Bob. If all events (like **A**) in Alice's past or present at **O** have happened, are fixed, or are real, then the principle of relativity suggests that we must also extend the same courtesy to Carol; and so simultaneous with the fixed and real event **A** (Carol's walking towards Earth at exactly the point at which Alice's plane of simultaneity intersects the history of Andromeda) is the event **C** (and so fixed and real), the intersection of Carol's plane of simultaneity with Earth, which is in the future of *both* Alice and Bob. It is easy to see that, by adjusting the speeds of Alice and Carol, any event to the future of **O** can be shown to be fixed or real or inevitable. But **O** itself was just an arbitrarily chosen point in the spacetime. “It begins to seem that if anything is definite at all,” we might echo Penrose, “then the entire space-time must indeed be definite! There can be no ‘uncertain’ future.” (p. 304)

Roberto Torretti (1983, p. 249) calls the resulting view of the definiteness or fixity of all events in the spacetime *chronogeometrical determinism.* A slightly better name might be *chronogeometrical fatalism*, as we will see below. In order to see more clearly, however, what has gone wrong in the argument above, it will be useful first to look more closely at the problems attendant upon trying to import our commonsense or classical intuitions about time into the understanding of Minkowski spacetime and then to describe briefly the structures peculiar to that spacetime itself. To begin with the first task, one of the

most notable attempts to bring our time into Minkowski spacetime is to be found in Sellars (1962), a determined attempt by one of the most profound systematic metaphysicians of the latter half of the 20th century.

3.1 Relativizing the Present

Wilfrid Sellars believed that the various invariant or observer-*independent* elements of Minkowski spacetime (like the light cone structure to be described below) that are typically given primary consideration in treatments of relativity from a spacetime perspective are abstractions from and secondary to the ‘perspectival’ pictures, the myriad of coordinate systems or reference frames. When it comes to time, however, he believed there is something even more fundamental than these perspectives:

> …we must distinguish between a moment, t, and the event of the moment's being present with respect to a given perspective and, above all, between the event of the moment's being present with respect to a given perspective and the event of the moment's being *present.* The latter, of course, is the essential feature of a temporal picture of the world. (577)

While there is in Sellars' paper a lengthy and illuminating series of reflections on the relation between events, facts, and substances, there is no guidance offered on the relation between a moment's being present with respect to a given perspective and a moment's simply being present, a concept which is ill-formed from a relativistic point of view. If this latter is indeed an essential feature of a temporal picture of the world, then special relativity does not provide us with a temporal picture of the world. If the world *is* fundamentally temporal in the way that Sellars insists it is, then (at least as far a special relativity as a representation of that world is concerned), Sellars' famous scientific realism is compromised.

Even though Sellars' conservative attempt to import pre-relativistic categories into Minkowski spacetime fails, there are some useful lessons to learn from it. First, Sellars is careful to distinguish between events as things that happen or occur or take place and the ‘events’ (the use of single quotes is Sellars') that are basic in relativity. The latter are just spacetime points. They do not take place or occur, and they are not the relata in causal relations, whereas events are. (But cf. Tooley (1997, Chapter 9)) While it is not clear what precisely Sellars took the distinction to be, he is careful to mark a distinction between events and ‘events’.

Sellars also presents a distinction between what he calls (p. 586) *categorial existence statements* and what, for lack of a better term, I will call *non-categorial existence statements.* The former invoke frameworks, like the framework of substances or the framework of ‘events’, the frameworks that Sellars takes great pains to compare in his essay. He is inclined towards a view he credits (without source) to Carnap that to say that, for instance, ‘Things exist’ is to make the metalinguistic claim that there are thing words in our language L now. This use of ‘exist,’ claims Sellars, has no (future or past) tensed contrast.

Non-categorial existence statements, on the other hand, assert the existence of individuals or less general kinds in a fully tensed fashion. Sellars would construe them in the following way (p. 592):

> *a* be existent { before *now*, *now*, after *now* } $\equiv$
> $\exists x$(*x* be { before *now*, *now*, after *now* } *and* *x* be $\Phi_1,\ldots,\Phi_n$ *and*
> 'Φ_1',…,'Φ_n' be our criteria *now* for [being] '*a*')

Leaving aside Sellars' idiosyncratic way of construing existence statements, if a distinction like the one indicated here can be made, then it would be perfectly coherent to indicate that one is adopting or working in the framework of 'events' by asserting that 'events exist' (in the categorial sense) without being committed to the "tenseless existence" of particular 'events,' which may be past, present, or future (in the non-categorial sense).

It has sometimes been thought that commitment to a spacetime framework, as is often explicit in treatments of special relativity, is tantamount to commitment to eternalism, since to say that spacetime points exist seems inconsistent with saying that some spacetime points are future and so do not exist yet or are past and so exist no longer. *If* some distinction of the type just sketched can be made between categorial and non-categorial existence statements, then eternalism is not a straightforward consequence of adopting the spacetime viewpoint.[6]

Granting Sellars all the distinctions that he wishes, however, does not give him the tools to avoid the central problem sketched above. Since the problem is, in one form or another, the problem that any view that tries to define a notion of becoming in Minkowski spacetime must address, it is worth examining it a bit more closely. Sellars wrote (p. 591):

> … in the case of an 'event' framework, a primary temporal picture is a picture with a *now*. And even if one observer's *now* is another observer's *then*, or one observer's simultaneous cross sections of the world are another observer's sets of differently dated 'events',… each of their *now*-pictures is a primary picture, and the purely topological picture (which includes the measurements performed by *S* and *S'* as topological facts) which is common to them is not *the primary picture* of the world construed as a system of 'events,' but merely a topological abstraction common to the various primary pictures; and the topologically formulated location of individual events in the topological picture is merely the topologically invariant features of the criteria which identify these 'events' in a primary picture.

In this quote Sellars is using the term 'topological' where one would now normally use the term 'geometric', and he is forcefully reiterating his view that the spacetime manifold of 'events' is merely an abstraction from the infinity of distinct *primary* now-pictures of individual observers.

The first question one will surely want to ask about this view is: how can an infinity of distinct "now-pictures" each be primary? No answer is forthcoming. The second, and more troubling question, is: how can this infinity of distinct "now-pictures" be related to the traditional metaphysical views under discussion? What, in short, is the connection (if any) between the temporal notions implicit in each of the

pictures and existence of the past, present, and future? The striking fact about Sellars' schema above for ‘a be existent *now*’ is that it is *not* relativized to a reference frame, coordinate system or “observer” and so is not meaningful relativistically. The definition gives us no guidance as to how to parcel out existence to elements in the infinity of reference frames that are admissible at a spacetime point.

If the definition or schema above were relativized to frames F, F', etc., so as to connect existence to relativistically acceptable "primary now-pictures", its interpretation would be either unhelpful or mysterious. Consider the following modification of Sellars' schema above:

> *a* be existent *now* in *F* ≡
> ∃*x*(*x* be *now* in *F and x* be $\Phi_1, \ldots \Phi_n$ *and*
> ‘Φ_1,’…,‘Φ_n’ be our criteria *now* for ‘*a*’)

Suppose it is not the case that *a* be existent *now* in some other frame F'. It seems as if this difference must result from *a*'s being simultaneous with some spacetime point **O**, say, in F while not being simultaneous with the same point **O** as coordinatized in F'. But on this reading Sellars' schema is just a round-about way to indicate that simultaneity is relative--the point of departure for our metaphysical questions rather than the answer to any.

The schema looks as if it is meant to do something more, to connect temporal notions to existence. But if so, how is existence relative to a frame to be understood? Classical presentism, for instance, wishes to identify existence with present existence or existence *now*. Since the present is relativized to frames in special relativity, may not existence be relativized to frames as well? This is a difficult notion to understand or accept. Kurt Gödel (1949, p. 558) said flatly, “The concept of existence … cannot be relativized without destroying its meaning completely.” Is the concept of existence, then, like the concept of truth, which, when relativized (as true-for-me, true-for-you), comes to something more like belief than truth? Or is it like simultaneity, about which thoughtful persons a century or so ago might have made pronouncements much like Gödel's? This difficult and fundamental question has by no means been resolved.

Were this question resolved in favor of the relativization of existence, what would be the import of a relativized version of presentism? It would have to hold that what existed changed radically with one's state of motion. Certain events (say on Mars or a planet orbiting a distant star) may be existent for you now, sitting at your computer screen or reading a printout, but other events will replace those as existent should you decide to walk one way or another. This seems (once again) less like an interesting metaphysical insight than a restatement of the relativity of simultaneity. Possibilism is not better off in this regard, for it relies on a metaphysically distinguished present to separate the real from the potential. (See the symposium "The Prospects for the Present in Spacetime Theories" in Howard (2000) for further arguments and references.)

To sum up, then, Sellars' attempt to tie existence to temporal notions, when properly relativized, is either a bland re-statement of what special relativity tells us already about simultaneity or an opaque statement

about relativized existence. This dilemma confronts any attempt to import pre-relativistic notions in Minkowski spacetime. Let us, then, turn to efforts to understand Minkowski spacetime in a different way, efforts that will help clarify the puzzling argument about the Andromedean invasion presented above.

3.2 Chronogeometrical Fatalism Again

We have said much about the relativity of simultaneity above but little directly about the invariance of the speed of light. We must now rectify that situation.

Imagine that at some point **O** of the spacetime an idealized point-sized flashbulb flashes for (literally) an instant. It follows from the invariance of the speed of light that Alice, passing through **O** as above, will find herself at the center of a sphere of photons. The radius of the sphere expands with speed *c*. (It follows that Bob, also passing through **O** but moving with some constant velocity with respect to Alice, must find himself also at the center of such a sphere, even though he and Alice are walking away from each other. Such is relativistic life!) If we try to diagram this situation, it is helpful to suppress one spatial dimension, as we have in all the figures above, and so the two-dimensional cut through the expanding sphere looks like an expanding circle, which becomes a cone when that growth is plotted vertically up the diagram (and so is called *the light cone.*) More precisely, this figure is just half the light cone. If two photons (restricting ourselves to two dimensions now) converged on point **O** from opposite directions, the lines indicating their histories would mark the other half, the past lobe, of the light cone.[7]

The light cone exists at each point of the spacetime and is an invariant structure. Since the speed of light is an invariant quantity, all “observers” agree as to which points of the spacetime are illuminated by the popping of the flashbulb at **O**. Furthermore, as special relativity is standardly understood, the speed of light is a limiting speed. No material particle can be accelerated from a speed less that *c* to a speed equal to or greater than *c*. Electromagnetic radiation (including light) always propagates in a vacuum at speed *c*. (To see why *c* is held to be limiting velocity, speed, see Mermin (1968, Chapter 15) and Nahin (1999, pp. 342-353 and Tech Note 7.) Given these suppositions, the light cone structure divides all spacetime into three distinct sorts of regions relative to each spacetime point **O**. (See chapters 5 and 6 of Geroch (1978) for a thorough discussion.)

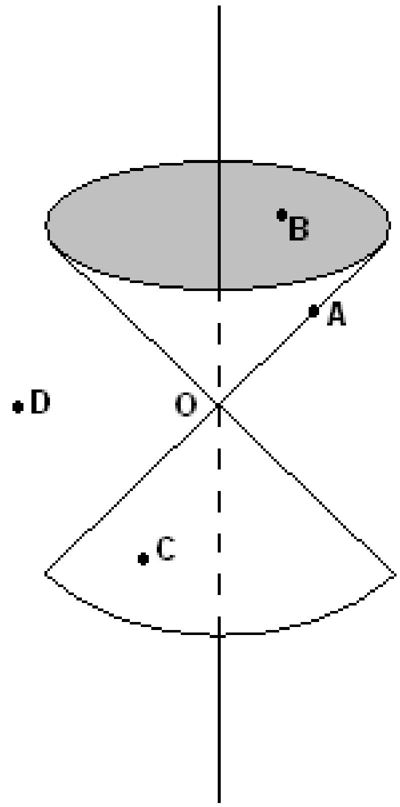

Figure 3. The Light Cone

First, there are the points from which a photon may travel to **O** or which may be reached by a photon from **O**. We say that these points are *lightlike separated* from **O**. If a photon can travel from **O** to **A**, we can indicate this briefly by writing **O** < **A**. In this case, **A** lies on the future light cone of **O**.

Second, there are the points inside (rather than on) the future or past light cone of **O**. We say that these points are *timelike separated* from **O**. If **B** is a point in the spacetime timelike separated from **O** and future to it (that is, inside **O**'s future light cone), then a material particle travelling at some relativistically acceptable speed (that is, less than *c*) can travel from **O** to **B**. Similarly, a material particle at a point inside the past light cone of **O**, can travel at some speed less than *c* from **C** to **O**. In this case we write **C** << **O**; in the former case, **O** << **B**.

Finally, there are the points of the spacetime that are neither in nor on the light cone of **O**. We say that such points are *spacelike separated* from **O**. If **D** is spacelike separated from **O**, then no light signal and no material body can travel from **O** to **D** or *vice versa*, because such travel would require superluminal speed. If one makes the natural assumption that information and causal influence are propagated by electromagnetic signals and material particles, then if **D** is spacelike separated from **O**, events or occurrences at **O** can have no causal influence at all on events at **D**.

We have reached this last conclusion by means of quite straightforward reasoning from the invariance of the speed of light. But consider the following observation of Torretti (1983, p. 247):

> Before Einstein … nobody appears to have seriously disputed that any two events might be

> causally related to each other, regardless of their spatial and temporal distance. The denial of this seemingly modest statement is perhaps the deepest innovation in natural philosophy brought about by Relativity. It has completely upset our traditional views of time, space, and causality …

As one illustration of how our traditional views of time and causality are upset by restricting the propagation of causal influence to the light cone structure, let us revisit the reasoning of the example of the Andromedean invasion that we used to illustrate and motivate chronogeometrical fatalism. We may be able to see now that this reasoning is not so compelling as it first seemed, and we may be able to see why some philosophers have proposed that we look at becoming in Minkowski spacetime in a way quite different from the traditional way.

To make the exposition easier, let us add to the story of the Andromedean invasion a fourth observer, Ted, who is at rest with respect to Earth (and so also Andromeda) at the spot where Alice and Bob meet. Ted too defines a coordinate system or frame of reference, and there is a point at Andromeda (We can call it **D**) that (in Ted's frame) is simultaneous with the meeting of Alice and Bob and Ted. To make our exposition easier still, let us suppose that Alice and Bob and Ted all set their clocks to read 0 at the instant at which they all meet.[8] Let us focus on **D**.

Ted (at the meeting of Alice and Bob) assigns to **D** the time 0, since it is simultaneous (in his frame) with his time 0. Alice assigns **D** (roughly) the time -3 days, whereas Bob assigns it time (roughly) +3 days. **D** is, of course, spacelike separated from **O**, and we have been at pains to explain that from a special relativistic standpoint this spacelike separation precludes the (physical) possibility that there is any causal influence upon **D** of the events at **O**. Once the labelling of spacetime points like **D** with coordinates is complete, what further content is there, what further could be meant, by adding that for Alice and Ted **D** is real or fixed? If there is indeed no further content, then what possible implications with regard to ‘reality’ or ‘fixity’ or ‘determinateness’ can be drawn from the fact that Bob labels this point with a positive number, Alice labels it with a negative number, and Ted labels it with 0?[9]

A good text in special relativity will sooner or later prove that for *any* pair of spacelike separated points (but let us continue to call them **O** and **D**) there is precisely one admissible coordinate system (with **O** as origin) in which **O** and **D** are simultaneous, an infinity of admissible coordinate systems in which **D** is assigned a positive number (that is, in which **O** occurs before **D**), and an infinity of other admissible coordinate systems in which **D** is assigned a negative number (that is, in which **D** occurs before **O**). What metaphysical significance could be gleaned from the fact that some observers (the usual anthropomorphized way to refer to admissible coordinate systems) at **O** must assign positive times, some negative times, and one time 0 to the distant event **D**, which, again, can not be influenced by and can not itself influence the events at **O**, according to special relativity at least?

Inability to provide any positive answer to this question can motivate a different approach to conceptualizing becoming in Minkowski spacetime, an approach presented by the philosopher Howard Stein (1968, 1991). The basic idea of this approach is to begin from or to define concepts in terms of the

geometric structure intrinsic to the spacetime. In the present case, this approach leads one to try to define ‘becoming’ in terms of spacetime points and light cones. Pre-relativistically, ‘has become’ is defined relative to a plane of simultaneity. We have seen the limitations of the notion of a plane of simultaneity in special relativity. Stein begins, then, by proposing that one defines the relation of ‘having become’ or ‘already definite’ with respect to spacetime points. A two-place relation schematically written as *Rxy* will be intended to capture the idea that point *y* has already become or is definite with respect to point *x*.

There are two other formal features that this relation *R* should possess. It should be *transitive* -- that is, if *z* has already become with respect to *y* and *y* has already become with respect to *x*, then it seems reasonable to require that *z* has already become with respect to *x*. It should also be *reflexive* -- that is, is seems reasonable to require that *x* has become with respect to *x* itself.

(We can indicate these conditions briefly as (1) *Rzy* and *Rxz* entail *Rxy*, for all *x*, *y*, *z* and (2) *Rxx*, for all *x*.)

Finally, Stein proposes that the relation *R* not hold between every two points in the spacetime. That is, he proposes that given some choice of spacetime point *x*, there is at least one distinct point *y* that has not become, that is not already definite, with respect to *x*. But is there any such relation, any relation that has all these intuitively desirable characteristics? The answer is *yes*. The relation is that between a point *x* and each point in or on its past light cone.[10] If one can accept that the relation *Rxy* represents in special relativity the notion of becoming (or, having become), then the existence of the relation specified and found by Stein is a formal refutation of the Rietdijk-Putnam-Penrose argument for chronogeometric fatalism.

It is this last issue, of course, that is controversial. Stein, who wishes to tie his definitions of temporal concepts to intrinsic geometric structure, holds that “in Einstein-Minkowski space-time *an event's present is constituted by itself alone.*” (1968, p. 15) If one wishes to include even *one* other event in an event's present--that is, if one specifies that for each point *x* there must be one other distinct point *y* such that not only *Rxy* but also *Ryx*--then the only relation that satisfies this *desideratum* and the other conditions specified by Stein is the universal relation.[11]

Callender (2000, S592) remarks that requiring that an event‘s present must contain at least one event distinct from it, which he calls the *non-uniqueness condition*, “seems the thinnest requirement one might put on becoming.” He would then not accept Stein's relation *R* as representing a genuine relation of becoming since it fails to meet this condition, but then he also must accept the conclusion of the Rietdijk-Putnam-Penrose argument, since the only alternative to *R* is the universal relation. If one wishes to evade chronogeometric fatalism, as far as the special theory of relativity is concerned, then it seems there is no alternative to accepting Stein's relation *R* as representing a genuine relation of becoming and to considering that an event's present is constituted by itself alone. It is a truism that the relativistic revolution in physics has profound implications for our concepts of space and time. This last dilemma shows why that truism is true.

There may seem to be an insuperable obstacle to accepting Stein's relation *R* as representing a genuine relation of becoming. *R* is supposed to represent becoming, but the light cone structure of Minkowski spacetime, in terms of which it is defined, is inert. This reaction was voiced, for instance, by Palle Yourgrau, who wrote that “Stein's mistake is to adduce a *structural* property as what ‘justifies the use of our notion of *“becoming”* in relativistic spacetime.”’ (1999, p. 77) If Yourgrau has put his finger on a “mistake”, then it is a “mistake” at the very heart of Stein's effort. There are, however, a few remarks to be made on this score.

First, there have been attempts to articulate positions like Stein's that try to account for passage in terms of geometric structure and that seem to incorporate more dynamic elements, exploiting the fact that persistent objects or substances (including “observers”) are represented by timelike world lines, rather than by points. The mathematician G. J. Whitrow (1980, p. 348) wrote:

> At a given instant *E* on the world line of an observer *A* (who need not be regarded as anything more than a recording instrument), all the events from which *A* can have received signals lie within the backwards-directed light cone with its vertex at *E*… . Signals from events [outside the light cone at *E*] can only reach *A* after the event *E*, and when they do reach *A* they will then lie within *A*'s backward-directed light cone at that instant. The passage of time corresponds to the continual advance of this light cone.

The physicist-philosopher Abner Shimony, in responding to the claim that special relativity shows that becoming is subjective or “mind-dependent,” wrote (1993, p. 284):

> Something fleeting does indeed traverse the world line, but that something is not subjective; it is the transient *now,* which as a matter of objective fact is momentarily present and thereafter is past.

In the felicitous phrase of Park (1971), we have here two different sorts of *animated Minkowski diagram.* Each seems to involve a kind motion, of the light cone or of the transient *now* advancing along a world line. Our initial restrictions on accounts of transience inspired by Broad's arguments should make us wary of invoking motion to account for passage. Park, moreover, sees no benefit to adding the animation.

> I want now to make the vital point that the animated diagram may be more intuitive, or more picturesque, or make better cinema than the atemporal one, but that it contains no more specific, verifiable information. All of the science of dynamics, that is, all we know about how complex systems (including ourselves) behave and interact, is already represented on the atemporal Minkowski diagram.

The non-animated Minkowski diagram may be “static”, but, as Park points out, the static diagram *represents* the evolution in (proper) time of systems along their world lines. The diagram, if Park is correct, need not itself be animated to represent dynamical phenomena. If Park is correct, then what Yourgrau called a “mistake” is in fact a virtue of Stein's account, that he makes no attempt to animate his

geometric *picture* but leaves whatever transience there may be in what it depicts.

Stanford Encyclopedia of Philosophy
Notes to Being and Becoming in Modern Physics

Notes

1. As translated in Wheelwright (1960). The quote by Parmenides in what follows is also from this volume.

2. Many recent papers on these issues are collected in Oaklander and Smith (1994). Gale (1967) has some good older papers and a useful bibliography.

3. There are many excellent non-technical introductions to the special theory. Two fine books that are currently available are Mermin (1968) and Born (1962). A more demanding introduction mathematically is Taylor and Wheeler (1963). An excellent philosophical discussion is Chapter IV of Friedman (1983).

All the concepts needed for the present discussion are outlined briefly in the opening paragraphs of section 4 of Shimony (1993), but there is no substitute for working through in detail at least one presentation of the special theory at whatever level of mathematical sophistication one is equipped to handle.

4. While most popular presentations of special relativity explicitly employ only these two assumptions, Friedman (1983) points out that another assumption of a more technical nature, the flatness of Minkowski spacetime, is needed in order to derive all the characteristic results of the theory. We will ignore this refinement here.

One should note, however, that the two assumptions explicitly made are assumptions concerning *invariance*--the invariance of the speed of light and the laws of physics. That certain other quantities classically thought to be invariant turn out not to be so in special relativity has sometimes obscured the fact that there is a fundamental invariant special relativisic four-dimensional quantity called *the spacetime interval* that will enter our considerations in due course.

5. Hans Reichenbach indicated the same view in 1925. See Grünbaum (1973, p. 318).

6. Whether this suggested distinction overlaps or is independent of the distinction between tensed and tenseless uses of ‘is’ invoked above in the section on Newtonian Spacetime is an open question. Questions about the viability of this distinction are connected to deep questions in ontology and philosophy of language on which Carnap, Quine, and Sellars differed. See the discussion in Jay Rosenberg's entry in this Encyclopedia, Wilfrid Sellars.

7. Minkowski spacetime is a *time orientable* manifold. If one chooses one of the two lobes of the light cone at a point **O** to be, say, future, that choice can be extended smoothly throughout the whole of the spacetime. We say nothing as to how this choice is to be made in this entry, but we assume that it has been, somehow, made.

8. The three are free to choose **O** as the origin of each of their coordinate systems and to assign it spatial coordinate (0,0,0) and temporal coordinate 0. But what position and time values are assigned by each of them to other spacetime points now follows rigorously from the rules, the Lorentz transformations, of special relativity.

9. It is the fact the Rietdijk-Putnam-Penrose argument for the fixity of the future does not rely on features of natural laws or causation that leads me to call the thesis chronogeometric *fatalism* rather than chronogeometric *determinism.* Determinist and fatalist arguments have the same conclusion, that the future is somehow fixed and not within our control, but the former do so from causal or nomological considerations while the later do not.

10. Briefly, Rxy iff ($y < x$ or $y << x$). Clifton and Hogarth (1995) point out the relation betwen x and each point in (but not on) its past light cone also satisfies all the criteria of adequacy specified in the text.

11. This result is implicit in the proofs offered by Stein and by Clifton and Hogarth. It is made explicitly in Callender (2000).

The Experience and Perception of Time

We see colours, hear sounds and feel textures. Some aspects of the world, it seems, are perceived through a particular sense. Others, like shape, are perceived through more than one sense. But what sense or senses do we use when perceiving time? It is certainly not associated with one particular sense. In fact, it seems odd to say that we see, hear or touch time passing. And indeed, even if all our senses were prevented from functioning for a while, we could still notice the passing of time through the changing pattern of our thought. Perhaps, then, we have a special faculty, distinct from the five senses, for detecting time. Or perhaps, as seems more likely, we notice time through perception of other things. But how?

Time perception raises a number of intriguing puzzles, including what it means to say we *perceive* time. In this article, we shall explore the various processes through which we are made aware of time, and which influence the way we think time really is. Inevitably, we shall be concerned with the psychology of time perception, but the purpose of the article is to draw out the philosophical issues, and in particular whether and how aspects of our experience can be accommodated within certain metaphysical theories concerning the nature of time and causation.

What is ‘the perception of time’?

The very expression ‘the perception of time’ invites objection. Insofar as time is something different from events, we do not perceive *time* as such, but changes or events *in* time. But, arguably, we do not perceive events only, but also their temporal relations. So, just as it is natural to say that we perceive spatial distances and other relations between objects (I see the dragonfly as hovering above the surface of the

water), it seems natural to talk of perceiving one event following another (the thunderclap as following the flash of lightening), though even here there is a difficulty. For what we perceive, we perceive as *present*-as going on right now. Can we perceive a relation between two events without also perceiving the events themselves? If not, then it seems we perceive both events as present, in which case we must perceive them as simultaneous, and so not as successive after all. There is then a paradox in the notion of perceiving an event as occurring after another, though one that perhaps admits of a straightforward solution. When we perceive B as coming after A, we have, surely, ceased to perceive A. In which case, A is merely an item in our memory. Now if we wanted to construe 'perceive' narrowly, excluding any element of memory, then we would have to say that we do not, after all, perceive B as following A. But in this article, we shall construe 'perceive' more broadly, to include a wide range of experiences of time that essentially involve the senses. In this wide sense, we perceive a variety of temporal aspects of the world. We shall begin by enumerating these, and then consider accounts of how such perception is possible.

Kinds of temporal experience

There are a number of what Ernst Pöppel (1978) calls 'elementary time experiences', or fundamental aspects of our experience of time. Among these we may list the experience of (i) duration; (ii) non-simultaneity; (iii) order; (iv) past and present; (v) change, including the passage of time. It might be thought that experience of non-simultaneity is the same as experience of time order, but it appears that, when two events occur very close together in time, we can be aware that they occur at different times without being able to say which one came first (see Hirsh and Sherrick (1961)). We might also think that perception of order was itself explicable in terms of our experience of the distinction between past and present. There will certainly be links here, but it is a contentious question whether the experience of *tense*-that is, experiencing an event as past or present-is more fundamental than the experience of order, or vice versa, or whether indeed there is such a thing as the experience of tense at all. This issue is taken up below. Finally, we should expect to see links between the perception of time order and the perception of motion if the latter simply involves perception of the order of the different spatial positions of an object. This is another contentious issue that is taken up below.

Duration

One of the earliest, and most famous, discussions of the nature and experience of time occurs in the autobiographical *Confessions* of St Augustine. Augustine was born in Numidia (now Algeria) in 354 AD, held chairs in rhetoric at Carthage and Milan, and become Bishop of Hippo in 395. He died in 430. As a young adult, he had rejected Christianity, but was finally converted at the age of 32. Book XI of the *Confessions* contains a long and fascinating exploration of time, and its relation to God. During the course of it Augustine raises the following conundrum: when we say that an event or interval of time is short or long, what is it that is being described as of short or long duration? It cannot be what is past, since that has ceased to be, and what is non-existent cannot presently have any properties, such as being long. But neither can it be what is present, for the present has no duration. (For the reason why the present must be regarded as durationless, see the section on the specious present, below.) In any case, while an event is

still going on, its duration cannot be assessed.

Augustine's answer to this riddle is that what we are measuring, when we measure the duration of an event or interval of time, is in the memory. From this he derives the radical conclusion that time itself (or, at least, the past and future) is something in the mind. While not following Augustine all the way to his theory of the subjectivity of time, we can concede that the perception of temporal duration is crucially bound up with memory. It is some feature of our memory of the event (and perhaps specifically our memory of the beginning and end of the event) that allows us to form a belief about its duration. This process need not be described, as Augustine describes it, as a matter of measuring something wholly in the mind. Arguably, at least, we are measuring the event or interval itself, a mind-independent item, but doing so by means of some psychological process.

Whatever the process in question is, it seems likely that it is intimately connected with what William Friedman (1990) calls ‘time memory’: that is, memory of when some particular event occurred. That there is a close connection here is entailed by the plausible suggestion that we infer (albeit subconsciously) the duration of an event, once it has ceased, from information about how long ago the beginning of that event occurred. That is, information that is *metrical* in nature (e.g. ‘the burst of sound was very brief’) is derived from *tensed* information, concerning how far in the past something occurred. The question is how we acquire this tensed information. It may be direct or indirect, a contrast we can illustrate by two models of time memory described by Friedman. He calls the first the *strength model* of time memory. If there is such a thing as a memory trace that persists over time, then we could judge the age of a memory (and therefore how long ago the event remembered occurred) from the strength of the trace. The longer ago the event, the weaker the trace. This provides a simple and direct means of assessing the duration of an event. Unfortunately, the trace model comes into conflict with a very familiar feature of our experience: that some memories of recent events may fade more quickly than memories of more distant events, especially when those distant events were very salient ones (visiting a rarely seen and frightening relative when one was a child, for instance.) A contrasting account of time memory is the *inference model*. According to this, the time of an event is not simply read off from some aspect of the memory of it, but is inferred from information about relations between the event in question and other events whose date or time is known.

The inference model may be plausible enough when we are dealing with distant events, but rather less so for much more recent ones. In addition, the model posits a rather complex cognitive operation that is unlikely to occur in non-human animals, such as the rat. Rats, however, are rather good at measuring time over short intervals of up to a minute, as demonstrated by instrumental conditioning experiments involving the ‘free operant procedure’. In this, a given response (such as depressing a lever) will delay the occurrence of an electric shock by a fixed period of time, such as 40 seconds, described as the R-S (response-shock) interval. Eventually, rate of responding tracks the R-S interval, so that the probability of responding increases rapidly as the end of the interval approaches. (See Mackintosh (1983) for a discussion of this and related experiments.) It is hard to avoid the inference here that the mere passage of time itself is acting as a conditioned stimulus: that the rats, to put it in more anthropocentric terms, are successfully estimating intervals of time. In this case, the strength model seems more appropriate than the inference model.

The specious present

The term ‘specious present’ was first introduced by the psychologist E.R. Clay, but the best known characterisation of it was due to William James, widely regarded as one of the founders of modern psychology. He lived from 1842 to 1910, and was professor of philosophy at Harvard. His definition of the specious present goes as follows: ‘the prototype of all conceived times is the specious present, the short duration of which we are immediately and incessantly sensible’ (James (1890)). How long is this specious present? Elsewhere in the same work, James asserts ‘We are constantly aware of a certain duration-the specious present-varying from a few seconds to probably not more than a minute, and this duration (with its content perceived as having one part earlier and another part later) is the original intuition of time.’ This surprising variation in the length of the specious present makes one suspect that more than one definition is hidden in James' rather vague characterisation. One could define it, for example, as the extent of short-term memory, in which case it might well vary from person to person, and also from one sense modality to another. Or it might be the interval in which information is experienced as a single unit (say a sentence, or musical phrase)-a rather ambiguous and unsatisfactory definition. A quite different definition is this: the interval of time such that events occurring within that interval are experienced as present. This is how the specious present tends to be treated in recent discussions, though it is inconsistent with James' remark that we can discern earlier and later parts in the specious present. As we remarked at the beginning of this article, if two events are experienced as present, they are surely experienced as simultaneous.

Taking the specious present as defined by this third characterisation, the *doctrine of the specious present* holds that the group of events we experience at any one time as present contains successive events spanning an interval. The experienced present is ‘specious’ in that, unlike the objective present, it is an interval and not a durationless instant. The ‘real’ present, as we might call it, must be durationless for, as Augustine argued, in an interval of any duration, there are earlier and later parts. So if any part of that interval is present, there will be another part that is past or future. This definition needs to be tightened up a little, to distinguish the tendency of the mind to group together successive events from the familiar fact that light and sound travel at finite speeds, and so events experienced as present will in fact be past (the degree of pastness varying with distance). What matters, as far as the doctrine is concerned, is not when an event occurred, but when information from that event reached our sense organs. Thus, light beams from two events may reach the retina at slightly different times, and yet the two events be perceived as simultaneous.

A number of arguments have been advanced in favour of the doctrine of the specious present (see Mundle (1966)):

(A) We see things as moving, such as the second-hand of a clock, and ‘to see a second-hand moving is quite a different thing from "seeing" that a hour-hand has moved.’ (Broad (1923)) More formally:

> (1) What we see, we see as present.

(2) We see motion.

(3) Motion occurs over an interval.

Therefore: What we see as present occurs over an interval.

(B) If the experienced present were only an durationless instant, then we could not understand a spoken sentence, because what would be presented to the senses at any one point would only be a meaningless phoneme—indeed not even that, since any sound necessarily takes up time (Gombrich (1964)).

(C) If the experienced present were only a durationless instant, then we would not see pictures on the television screen or VDU of a computer, since these are built up from a moving electron beam. More generally, we would not see anything at all, since light itself is a motion (*Ibid.*).

However, the first two of these arguments are questionable (at least as arguments for the doctrine as we have characterised it; they may be more appropriate for other conceptions of the specious present). If events e_1 and e_2 are registered in a single specious present, then we perceive them both as present, and so as simultaneous. But we do not see, e.g., the successive positions of a moving object as simultaneous, for if we did we would see a blurred object and not a moving one. So (in response to A) to see an object as moving is not to see as present something that occurs over an interval. Similarly, we do not hear all the parts of a spoken sentence as simultaneous, for if we did it would be a meaningless jumble. So (in response to B) we do not hear all the parts of the sentence as present.

C, in contrast, appears to be sound, and does not involve the contradictory suggestion that we experience some things as both ordered and as present. When events occur sufficiently fast, such as the movement of the electron beam over the television screen, we simply fail to perceive the temporal order of certain components of our experience. In these cases, we see things as simultaneous when they are not simultaneously presented to our sensory apparatus, and that is the basis of the true doctrine of the specious present.

Past, present and the passage of time

The previous section indicated the importance of distinguishing between perceiving the present and perceiving something *as* present. We may perceive as present items that are past. Indeed, given the finite speed of the transmission of both light and sound (and the finite speed of transmission of information from receptors to brain), it seems that we only ever perceive what is past. However, this does not by itself tell us what it is to perceive something as present, rather than as past. Nor does it explain the most striking feature of our experience as-of the present: that it is constantly changing. The passage (or apparent passage) of time is its most striking feature, and any account of our perception of time must account for this aspect of our experience.

Here is one attempt to do so. The first problem is to explain why our temporal experience is limited in a way in which our spatial experience is not. We can perceive objects that stand in a variety of spatial

relations to us: near, far, to the left or right, up or down, etc. Our experience is not limited to the immediate vicinity (although of course our experience is spatially limited to the extent that sufficiently distant objects are invisible to us). But, although we perceive the past, we do not perceive it as past, but as present. Moreover, our experience does not only appear to be temporally limited, it is so: we do not perceive the future, and we do not continue to perceive transient events long after information from them reached our senses. Now, there is a very simple answer to the question why we do not perceive the future, and it is a causal one. Briefly, causes always precede their effects; perception is a causal process, in that to perceive something is to be causally affected by it; therefore we can only perceive earlier events, never later ones. So one temporal boundary of our experience is explained; what of the other?

There seems no *logical* reason why we should not directly experience the distant past. We could appeal to the principle that there can be no action at a temporal distance, so that something distantly past can only causally affect us via more proximate events. But this is inadequate justification. We can only perceive a spatially distant tree by virtue of its effects on items in our vicinity (light reflected off the tree impinging on our retinas), but this is not seen by those who espouse a direct realist theory of perception as incompatible with their position. We still see the *tree*, they say, not some more immediate object. Perhaps then we should look for a different strategy, such as the following one, which appeals to biological considerations. To be effective agents in the world, we must represent accurately what is currently going on: to be constantly out of date in our beliefs while going about our activities would be to face pretty immediate extinction. Now we are fortunate in that, although we only perceive the past it is, in most cases, the very recent past, since the transmission of light and sound, though finite, is extremely rapid. Moreover, although things change, they do so, again in most cases, at a rate that is vastly slower than the rate at which information from external objects travels to us. So when we form beliefs about what is going on in the world, they are largely accurate ones. (See Butterfield (1984) for a more detailed account along these lines.) But, incoming information having been registered, it needs to move into the memory to make way for more up to date information. For, although things may change slowly relative to the speed of light or of sound, they do change, and we cannot afford to be simultaneously processing conflicting information. So our effectiveness as agents depends on our not continuing to experience a transient state of affairs (rather in the manner of a slow motion film) once information from it has been absorbed. Evolution has ensured that we do not experience anything other than the very recent past (except when we are looking at the heavens).

To perceive something as present is simply to perceive it: we do not need to postulate some extra item in our experience that is ‘the experience of presentness.’ It follows that there can be no ‘perception of pastness’. In addition, if pastness were something we could perceive, then we would perceive *everything* in this way, since every event is past by the time we perceive it. But even if we never perceive anything as past (at the same time as perceiving the event in question) we could intelligibly talk more widely of the experience of pastness: the experience we get when something comes to an end. And it has been suggested that memories-more specifically, *episodic memories*, those of our experiences of past events-are accompanied by a feeling of pastness (see Russell (1921)). The problem that this suggestion is supposed to solve is that an episodic memory is simply a memory of an event: it *represents* the event simpliciter, rather than the fact that the event is past. So we need to postulate something else which alerts us to the fact that the event remembered is past. An alternative account, and one which does not appeal to

any phenomenological aspects of memory, is that memories dispose us to form past-tensed beliefs, and is by virtue of this that they represent an event as past.

We have, then, a candidate explanation for our experience of being located at a particular moment in time, the (specious) present. And as the content of that experience is constantly changing, so that position in time shifts. But there is still a further puzzle. Change in our experience is not the same thing as experience of change. We want to know, not just what it is to perceive one event after another, but also what it is to perceive an event as occurring after another. Only then will we understand our experience of the passage of time. We turn, then, to the perception of time order.

Time order

How do we perceive precedence amongst events? A temptingly simple answer is that the perception of precedence is just a sensation caused by instances of precedence, just as a sensation of red is caused by instances of redness. Hugh Mellor (1998), who considers this line, rejects it for the following reason. If this were the correct explanation, then we could not distinguish between *x* being *earlier* than *y*, and *x* being *later* than *y*, for whenever there is an instance of one relation, there is also an instance of the other. But plainly we are able to distinguish the two cases, so it cannot simply be a matter of perceiving a relation, but something to do with our perception of the relata. But mere perception of the relata cannot be all there is to perceiving precedence. Consider again Broad's point about the second hand and the hour hand. We first perceive the hour hand in one position, say pointing to 3 o'clock, and later we perceive it in a different position, pointing to half-past 3. So I have two perceptions, one later than the other. I may also be aware of the temporal relationship of the two positions of the hand. Nevertheless, I do not perceive that relationship, in that I do not see the hand moving. In contrast, I do see the second hand move from one position to another: I see the successive positions *as* successive.

Mellor's proposal is that I perceive *x* precede *y* by virtue of the fact that my perception of *x* causally affects my perception of *y*. As I see the second hand in one position, I have in my short-term memory an image (or information in some form) of its immediately previous position, and this image affects my current perception. The result is a perception of movement. The perceived order of different positions need not necessarily be the same as the actual temporal order of those positions, but it will be the same as the causal order of the *perceptions* of them. Since causes always precede their effects, the temporal order perceived entails a corresponding temporal order in the perceptions.

In effect, Mellor's idea is that the brain represents time by means of time: that temporally ordered events are represented by similarly temporally ordered experiences. This would make the representation of time unique. (For example, the brain does not represent spatially separated objects by means of spatially separated perceptions, or orange things by orange perceptions.) But why should time be unique in this respect? In other media, time can be represented spatially (as in cartoons, graphs, and analogue clocks) or numerically (as in calendars and digital clocks). So perhaps the brain can represent time by other means. One reason to suppose that it must have other means at its disposal is that time needs to be represented in *memory* (I recall, both that a was earlier than b, and also the experience of seeing a occur before b) and

intention (I intend to F after I G), but there is no obvious way in which Mellor's ‘representation of time by time’ account can be extended to these.

On Mellor's model, the mechanism by which time-order is perceived is sensitive to the *time* at which perceptions occur, but indifferent to their *content* (what the perceptions are of). Daniel Dennett (1991) proposes a different model, on which the process is time-independent, but content-sensitive. For example, the brain may infer the temporal order of events by seeing which sequence makes sense of the causal order of those events. One of the advantages of Dennett's model is that it can account for the rather puzzling cases of ‘backwards time referral’, where perceived order does not follow the order of perceptions. (See Dennett (1991) for a discussion of these cases, and also Roache (1999) for an attempt to reconcile them with Mellor's account.)

The metaphysics of time perception

In giving an account of the various aspects of time perception, we inevitably make use of concepts that we take to have an objective counterpart in the world: the past, temporal order, causation, change, the passage of time and so on. But one of the most important lessons of philosophy, for many writers, is that there may be a gap, perhaps even a gulf, between our representation of the world and the world itself, even on a quite abstract level. (It would be fair to add that, for other writers, this is precisely *not* the lesson philosophy teaches.) Philosophy of time is no exception to this. Indeed, it is interesting to note how many philosophers have taken the view that, despite appearances, time, or some aspect of time, is unreal. In this final section, we will take a look at how two metaphysical debates concerning the nature of the world interact with account of time perception.

The first debate concerns the reality of tense, that is, our division of time into past, present and future. Is time really divided in this way? Does what is present slip further and further into the past? Or does this picture merely reflect our perspective on a reality in which there is no uniquely privileged moment, the present, but simply an ordered series of moments? *Tensed theorists* say that our ordinary picture of the world as tensed reflects the world as it really is: the passage of time is an objective fact. *Tenseless theorists* deny this. For them, the only objective temporal facts concern relations of precedence and simultaneity between events. (I ignore here the complications introduced by the Special Theory of Relativity, since tenseless theory-and perhaps tensed theory also-can be reformulated in terms which are compatible with the Special Theory.) Tenseless theorists do not deny that our tensed beliefs, such that that a cold front is *now* passing, or that Sally's wedding *was two years ago*, may be true, but they assert that what makes such beliefs true are not facts about the pastness, presentness or futurity of events, but tenseless facts concerning precedence and simultaneity (see Mellor (1998), Oaklander and Smith (1994)). On one version of the tenseless theory, for example, my belief that there is a cold front now passing is true because the passing of the front is *simultaneous with* my forming the belief. Now one very serious challenge to the tenseless theorist is to explain why, if time does not pass in reality, it appears to do so. What, in tenseless terms, is the basis for our experience as-of the passage of time?

The accounts we considered above, first of the temporal restrictions on our experience, and secondly of

our experience of time order, did not explicitly appeal to tensed notions. The facts we did appeal to look like purely tenseless ones: that causes are always earlier than their effects, that things typically change slowly in relation to the speed of transmission of light and sound, that our information-processing capacities are limited, and that there can be causal connections between memories and experiences. So it may be that the tenseless theorist can discharge the obligation to explain why time seems to pass. But two doubts remain. First, perhaps the tensed theorist can produce a simpler explanation of our experience. Second, it may turn out that supposedly tenseless facts are dependent upon tensed ones, so that, for example, *a* and *b* are simultaneous by virtue of the fact that both are *present*.

The second metaphysical issue that has a crucial bearing on time perception concerns causal asymmetry. The account of our sense of being located at a time which we considered under Past, present and the passage of time rested on the assumption that causation is asymmetric. Later events, it was suggested, cannot affect earlier ones, as a matter of mind-independent fact, and this is why we do not perceive the future, only the past. But attempts to explain the basis of causal asymmetry, in terms for example of counterfactual dependence, or in probabilistic terms, are notoriously problematic. One moral we might draw from the difficulties of reducing causal asymmetry to other asymmetries is that causal asymmetry is primitive, and so irreducible. Another is that that the search for a mind-independent account is mistaken. Perhaps causation in intrinsically symmetric, but some feature of our psychological constitution and relation to the world makes causation appear asymmetric. This *causal perspectivalism* is the line taken by Huw Price (1996). That causal asymmetry should be explained in part by our psychological constitution, in a way analogous to our understanding of secondary qualities such as colour, is a radical reversal of our ordinary assumptions, but then our ordinary understanding of a number of apparently objective features of the world—tense, absolute simultaneity—have met with similarly radical challenges. Now, if causal asymmetry is mind-dependent in this way, then we cannot appeal to it in accounting for our experience of temporal asymmetry—the difference between past and future.

But the facts of perception may themselves constitute a problem for perspectivalism over causal asymmetry. We will leave the topic of time perception with the following conundrum for proponents of causal perspectivalism. Consider the following causally ordered (but not directed) series:

$\Phi - \beta - \kappa$

Assuming, as perspectivalism holds, that causation is intrinsically symmetric, β stands in exactly the same causal relation to Φ as it does to κ. However, although not directed, the series is ordered in that the relation of causal betweenness holds between items. Thus β is causally between Φ and κ. But then, if this is so, it is not clear how perspectivalism could explain why the following principle holds:

If β is a perceptual experience, then it cannot have both Φ and κ as its object

This principle does not beg the question against perspectivalism by smuggling in an assumption about causal asymmetry. For it is surely a trivial fact about our perception of time that if A is experienced as occuring before B, A and B cannot be experienced as simultaneous. And it is surely an objective

(although non-trivial) fact that our experience of A will be causally between A and our experience of B. Now if perspectivalism cannot answer the challenge to explain the truth of the above principle, it seems that our experience of temporal asymmetry, insofar as it has a causal explanation, requires causation to be objectively asymmetric.

One strategy the causal perspectivalist could adopt (indeed, the only one available) is to explain the asymmetric principle above in terms of some objective non-causal asymmetry. Price, for example, allows an objective thermodynamic asymmetry, in that an ordered series of states of the universe will exhibit what he calls a thermodynamic gradient: entropy will be lower at one end of the series than at the end. We should resist the temptation to say that entropy increases, for that would be like asserting that a road goes uphill rather than downhill without conceding the perspectival nature of descriptions like ‘uphill’. Could such a thermodynamic asymmetry explain why perception points in one direction? That is a thought for the reader to ponder.

The Hole Argument

What is space? What is time? Do they exist independently of the things and processes in them? Or is their existence parasitic on these things and processes? Are they like a canvas onto which an artist paints; they exist whether or not the artist paints on them? Or are they akin to parenthood; there is no parenthood until there are parents and children? That is, is there no space and time until there are things with spatial properties and processes with temporal durations?

These questions have long been debated and continue to be debated. The hole argument arose when these questions were asked in the context of modern spacetime physics. In that context, space and time are fused into a single entity, spacetime, and we inquire into its status. One view is that spacetime is a substance, a thing that exists independently of the processes occurring within spacetime. This is spacetime substantivalism. The hole argument seeks to show that this viewpoint leads to unpalatable conclusions in a large class of spacetime theories. Spacetime substantivalism requires that we ascribe such a surfeit of properties to spacetime that neither observation nor even the laws of the relevant spacetime theory itself can determine which are the correct ones. Such abundance is neither logically contradictory nor refuted by experience. But there must be some bounds on how rich a repertoire of hidden properties can be ascribed to spacetime. The hole argument urges that spacetime substantivalism goes beyond those bounds.

The hole argument was invented for slightly different purposes by Albert Einstein late in 1913 as part of his quest for the general theory of relativity. It was revived and reformulated in the modern context by John^3 = John Earman x John Stachel x John Norton.

1. Modern Spacetime Theories: A Beginner's Guide

Virtually all modern spacetime theories are now built in the same way. The theory posits a manifold of events and then assigns further structures to those events to represent the content of spacetime. A standard example is Einstein's general theory of relativity. As a host for the hole argument, we will pursue one of its best known applications, the expanding universes of modern relativistic cosmology.[1]

Manifold of Events. Consider our universe, which relativistic cosmologies attempt to model. Events in the universe correspond to the dimensionless points of familiar spatial geometry. Just as a geometric point is a particular spot in a geometrical space, an event is a particular point in a cosmological space at a particular time. To be a four-dimensional manifold, the events must be a little bit more organized than they are if they merely form a set. That extra organization comes from the requirement that we can smoothly label the events with four numbers--or at least we can do this for any sufficiently small chunk of the manifold. These labels form coordinate systems. Figure 1 shows how a set of events may be made into a two dimensional manifold.

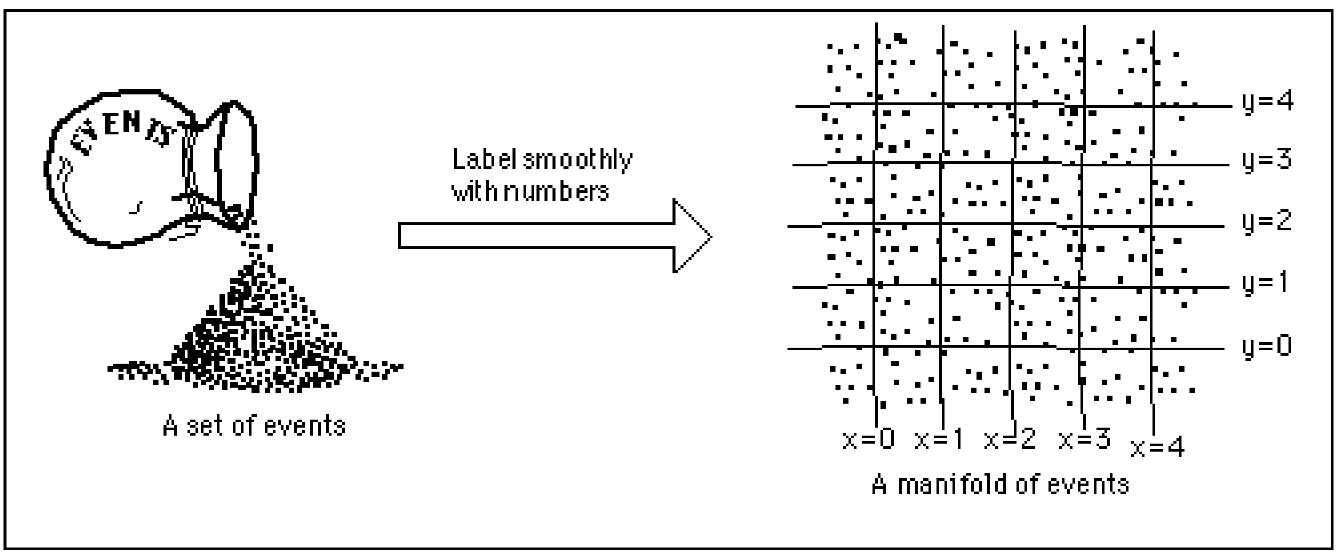

Figure 1. Forming a manifold of events

Metrical Structure and Matter Fields. In specifying that events form a four dimensional manifold, we have still not specified which events lie in the future and past of which other events, how much time elapses between these events, which events are simultaneous with others so that they can form three dimensional spaces, what spatial distances separates these events and many more related properties. These additional properties are introduced by specifying the metric field.

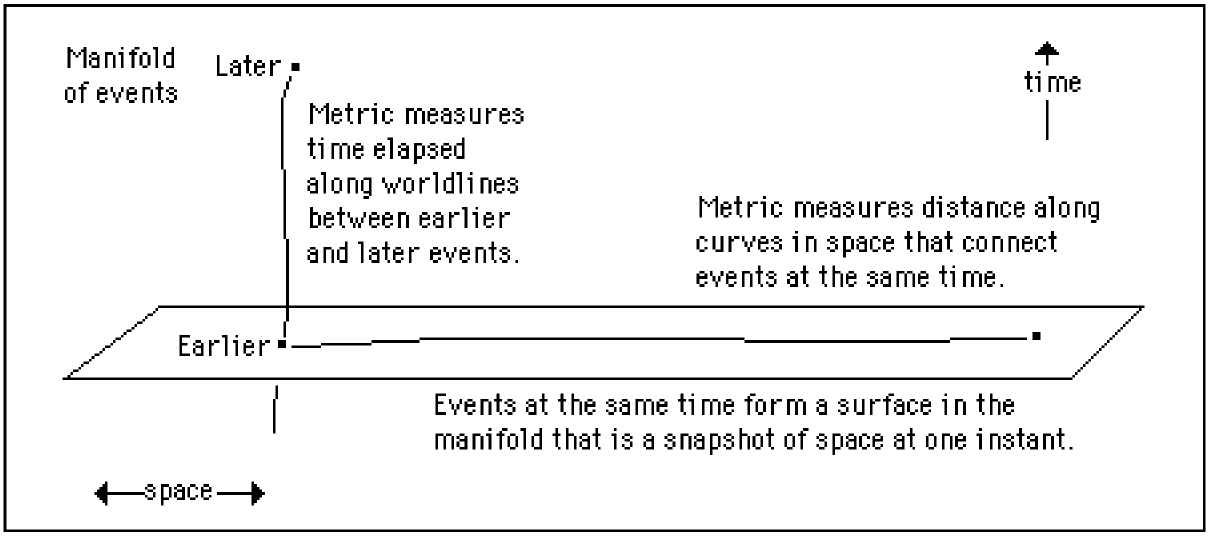

Figure 2. The function of the metric field.

Imagine all the curves in some spacetime and an exhaustive catalog of all the distances in space and duration elapsed in time between any two events on any curve that connects them. The information carried by the metric is just that catalog, reduced to a very much more compact form.

The matter of the universe is represented by matter fields. The simplest form of matter--the big lumps that make galaxies--can be represented by worldlines that trace out the history of each galaxy through time. In standard models, the galaxies recede from one another and this is represented by a spreading apart of the galactic worldlines as we proceed to later times.

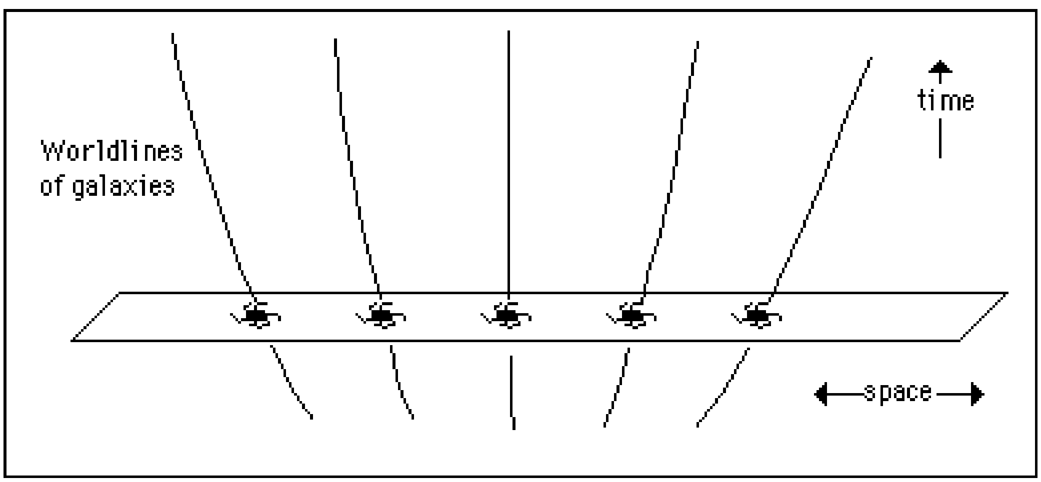

Figure 3. Galaxies in an expanding universe.

2. The Freedom of General Covariance

When Einstein first introduced his general theory of relativity in the 1910s, its novel feature was its general covariance. It was the first spacetime theory in which one was free to use arbitrary spacetime coordinate systems. This feature is now shared by virtually all modern formulations of spacetime

theories, including modern versions of special relativity and Newtonian spacetime theory. In the modern context, the freedom of general covariance is expressed in a more vividly geometric manner.[2] When we assemble a relativistic universe, we spread the metrical structure and matter fields over a manifold:

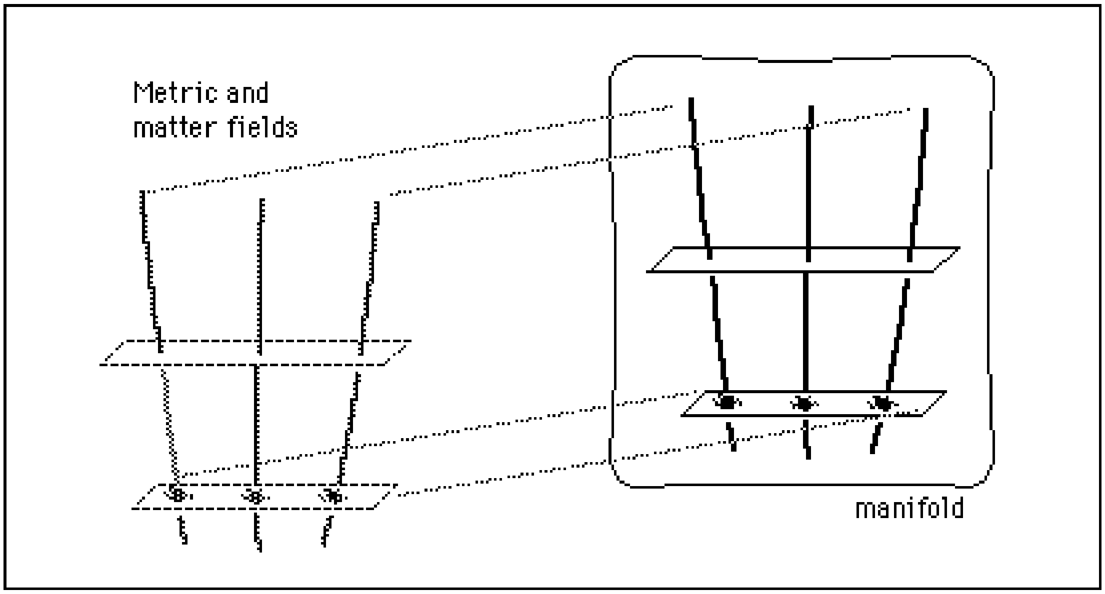

Figure 4. One way to spread metric and matter over the manifold.

What general covariance does is to license different spreadings of metric and matter fields. If the theory allows one spreading, such as that given in Figure 4, then through general covariance it allows any other that represents a smooth deformation of the original, such as shown in Figure 5:

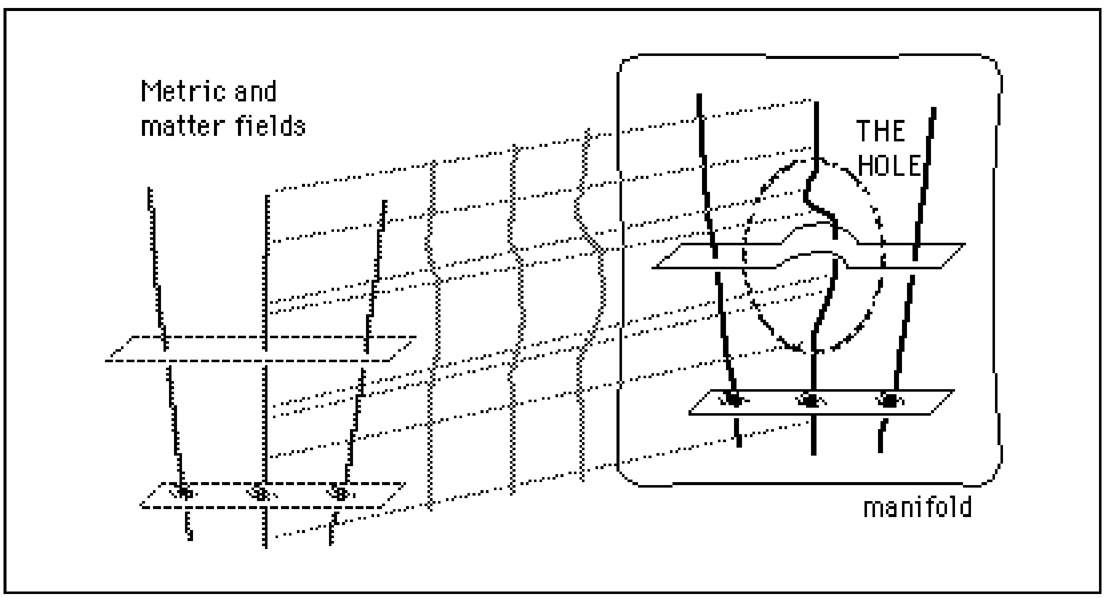

Figure 5. Another way to spread metric and matter over the manifold.

Figures 4 and 5 illustrate a hole transformation on the metric and matter fields. The dotted region is The Hole. The first distribution of metric and matter fields is transformed into the second in a special way. The transformation leaves the fields unchanged outside the hole; within it they have been spread

differently on the manifold; the spreadings inside and outside the hole join smoothly.[3]

3. The Preservation of Invariants

The two different spreadings share one vital characteristic upon which the hole argument depends: the two spreadings agree completely on all invariant properties. These invariant properties are, loosely speaking, the ones that are intrinsic to the geometry and dynamics, such as distance along spatial curves and time along worldlines of galaxies, the rest mass of the galaxy, the number of particles in it, as well as a host of other properties, such as whether the spacetimes are metrically flat or curved. While the fields are spread differently in the two cases, in invariant terms, they are the same.

This last result actually explains the prevalence of general covariance. The laws of a spacetime theory are typically stated as relations between invariant properties. Therefore if they are satisfied by one spacetime, they must also be satisfied by a transform of that spacetime that shares all the original's invariant geometric properties.

All observables can be reduced to invariants. For example, if one makes a journey from one galaxy to another, all observables pertinent to the trip will be invariants. These include the time elapsed along the journey, whether the spaceship is accelerating or not at any time in its journey, the age of the galaxy one leaves at the start of the trip and the age of the destination galaxy at the end and all operations that may involve signaling with particles or light pulses.

Therefore, since the two spreadings or distributions agree on invariants, they also agree on all observables and are observationally indistinguishable.

4. What Represents Spacetime? Manifold Substantivalism

We want to know whether we can conceive of spacetime as a substance, that is, as something that exists independently. To do this, we need to know what in the above structures represents spacetime. One popular answer to that question is that the manifold of events represents spacetime. We shall see shortly that this popular form of the answer is the one that figures in the hole argument. This choice is natural since modern spacetime theories are built up by first positing a manifold of events and then defining further structures on them. So the manifold plays the role of a container just as we expect spacetime does.[4]

The notion that the manifold represents an independently existing thing is quite natural in the realist view of physical theories. In that view one tries to construe physical theories literally. If formulated as above, a spacetime is a manifold of events with certain fields defined on the manifold. The literal reading is that this manifold is an independently existing structure that bears properties.

Appealing as manifold substantivalism once was, after one sees what trouble it causes, it becomes tempting to insist that the manifold of events lacks properties essential to spacetime. For example, there is no notion of past and future, of time elapsed or of spatial distance in the manifold of events. Thus one might be tempted to identify spacetime with the manifold of events plus some further structure that supplies these spatiotemporal notions. In relativistic cosmologies, that further structure would be the metrical structure. Readers who pursue this issue further will find that this escape from the hole argument sometimes succeeds and sometimes fails. In certain important special cases, alternative versions of the hole argument can be mounted against the manifold-plus-further-structure substantivalists. (See Norton 1988.)

In general relativity, there is a further problem with arguing that the metric field properly belongs to spacetime since it carries essential spatiotemporal properties. The metric field of general relativity also carries energy and momentum--the energy and momentum of the gravitational field. This energy and momentum is freely interchanged with other matter fields in spacetimes. It is the source of the huge quantities of energy released as radiation and heat in stellar collapse, for example. To carry energy and momentum is a natural distinguishing characteristic of matter contained within spacetime. So the metric field of general relativity seems to defy easy characterization as exclusively part of spacetime the container or matter the contained.

5. The Price of Spacetime Substantivalism

So far we have characterized the substantivalist doctrine as the view that spacetime has an existence independent of its contents. This formulation conjures up powerful if vague intuitive pictures, but it is not clear enough for interpretation in the context of physical theories. If we represent spacetime by a manifold of events, how do we characterize the independence of its existence? Is it the counterfactual claim that were there no metric or matter fields, there would still be a manifold of events? That counterfactual is automatically denied by the standard formulation which posits that all spacetimes have at least metrical structure. That seems too cheap a refutation of manifold substantivalism. Surely, there must be an improved formulation. Fortunately, we do not need to wrestle with finding it. For present purposes we need only consider a consequence of the substantivalist view and can set aside the task of giving a precise formulation of the substantivalist view.

In their celebrated debate over space and time, Leibniz taunted the substantivalist Newton's representative, Clarke, by asking how the world would change if East and West were switched. For Leibniz there would be no change since all spatial relations between bodies would be preserved by such a switch. But the Newtonian substantivalist had to concede that the bodies of the world were now located in different spatial positions, so the two systems were physically distinct.

Correspondingly, when we spread the metric and matter fields differently over a manifold of events, we are now assigning metrical and material properties in different ways to the events of the manifold. For example, imagine that a galaxy passes through some event E in the hole. After the hole transformation,

this galaxy might not pass through that event. For the manifold substantivalist, this must be a matter of objective physical fact: either the galaxy passes through E or not. The two distributions represent two physically distinct possibilities.

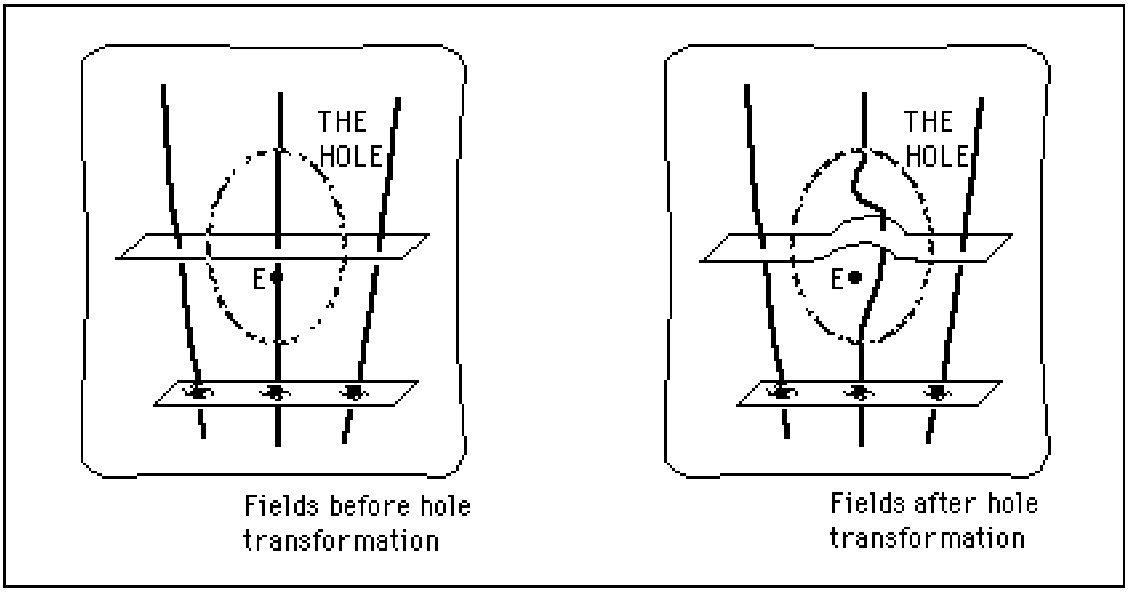

Figure 6. Does the galaxy pass through event E?

That is, manifold substantivalists must deny an equivalence inspired by Leibniz' taunt and is thus named after him:[5]

> **Leibniz Equivalence**. If two distributions of fields are related by a smooth transformation, then they represent the same physical systems.

6. Unhappy Consequences

We can now assemble the pieces above to generate unhappy consequences for the manifold substantivalist. Consider the two distributions of metric and matter fields related by a hole transformation. Since the manifold substantivalist denies Leibniz equivalence, the substantivalist must hold that the two systems represent distinct physical systems. But the properties that distinguish the two are very elusive.

We have already noticed that the two are observationally equivalent. So the substantivalist must insist that it makes a physical difference as to whether the galaxy passes through event E or not. But no observation can tell us if we are in a world in which the galaxy passes through event E or misses event E, for universes with either are observationally equivalent.

Worse, the physical theory of relativistic cosmology is unable to pick between the two cases. This is manifested as an indeterminism of the theory. We can specify the distribution of metric and matter fields throughout the manifold of events, excepting within the region designated as The Hole. Then the theory

is unable to tell us how the fields will develop into The Hole. Both the original and the transformed distribution are legitimate extensions of the metric and matter fields outside The Hole into The Hole, since each satisfies all the laws of the theory of relativistic cosmology. The theory has no resources which allow us to insist that one only is admissible.

It is important to see that the unhappy consequence does not consist merely of a failure of determinism. We are all too familiar with such failures and it is certainly not automatic grounds for dismissal of a physical theory. The best known instance of a widely celebrated, indeterministic theory is quantum theory, where, in the standard interpretation, the measurement of a system can lead to an indeterministic collapse onto one of many possible outcomes. Less well known is that it is possible to devise indeterministic systems in classical physics as well.

The problem with the failure of determinism in the hole argument is not the fact of failure but the way that it fails. If we deny manifold substantivalism and accept Leibniz equivalence, then the indeterminism induced by a hole transformation is eradicated. While there are uncountably many mathematically distinct developments of the fields into the hole, under Leibniz Equivalence, they are all physically the same. That is, there is a unique development of the physical fields into the hole after all. Thus the indeterminism is a direct product of the substantivalist viewpoint. Similarly, if we accept Leibniz equivalence, then we are no longer troubled that the two distributions cannot be distinguished by any possible observation. They are merely different mathematical descriptions of the same physical reality and so should agree on all observables.

We can load up any physical theory with superfluous, phantom properties that cannot be fixed by observation. If their invisibility to observation is not sufficient warning that these properties are illegitimate, finding that they visit indeterminism onto a theory that is otherwise deterministic in this set-up ought to be warning enough. These properties are invisible to both observation and theory; they should be discarded along with any doctrine that requires their retention.

7. The Hole Argument in Brief

In sum the hole argument amounts to this:[6]

> **1.** If one has two distributions of metric and matter fields related by a hole transformation, manifold substantivalists must maintain that the two systems represent two distinct physical systems.
>
> **2.** This physical distinctness transcends both observation and the determining power of the theory since:
> -- The two distributions are observationally identical.
> -- The laws of the theory cannot pick between the two developments of the fields into the hole.

3. Therefore the manifold substantivalist advocates an unwarranted bloating of our physical ontology and the doctrine should be discarded.

8. The History of the Hole Argument

8.1 Einstein Falls into the Hole...

The hole argument was created by Albert Einstein late in 1913 as an act of desperation when his quest for his general theory of relativity had encountered what appeared to be insuperable obstacles. Over the previous year, he had been determined to find a gravitation theory that was generally covariant, that is, whose equations were unchanged by arbitrary transformation of the spacetime coordinates. He had even considered essentially the celebrated, generally covariant equations he would settle upon in November 1915 and which now appear in all the text books.

Unfortunately Einstein had been unable to see that these equations were admissible. Newton's theory of gravitation worked virtually perfectly for weak gravitational fields. So it was essential that Einstein's theory revert to Newton's in that case. But try as he might, Einstein could not see that his equations and many variants of them could properly mesh with Newton's theory. In mid 1913 he published a compromise: a sketch of a relativistic theory of gravitation that was not generally covariant. (For further details of these struggles, see Norton (1984).)

His failure to find an admissible generally covariant theory troubled Einstein greatly. Later in 1913 he sought to transform his failure into a victory of sorts: he thought he could show that no generally covariant theory at all is admissible. Any such theory would violate what he called the Law of Causality--we would now call it determinism. He sought to demonstrate this remarkable claim with the hole argument.

In its original incarnation, Einstein considered a spacetime filled with matter excepting one region, the hole, which was matter free. (So in this original form, the term "hole" makes more sense than in the modern version.) He then asked if a full specification of both metric and matter fields outside the hole would fix the metric field within. Since he had tacitly eschewed Leibniz Equivalence, Einstein thought that the resulting negative answer sufficient to damn all generally covariant theories.

8.2 ...and Climbs out Again

Einstein struggled on for two years with his misshapen theory of limited covariance. Late in 1915, as evidence of his errors mounted inexorably, Einstein was driven to near despair and ultimately capitulation. He returned to the search for generally covariant equations with a new urgency, fueled in part by the knowledge that none other than David Hilbert had thrown himself into analysis of his theory. Einstein's quest came to a happy close in late November 1915 with the completion of his theory in

generally covariant form.

For a long time it was thought that Hilbert had beaten Einstein by 5 days to the final theory. New evidence in the form of the proof pages of Hilbert's paper now suggests he may not have. More important, it shows clearly that Hilbert, like Einstein, at least temporarily believed that the hole argument precluded all generally covariant theories and that the belief survived at least as far as the proof pages of his paper. (See Corry, Renn and Stachel 1997.)

While Einstein had tacitly withdrawn his objections to generally covariant theories, he had not made public where he thought the hole argument failed. This he finally did when he published what John Stachel calls the "point-coincidence argument." This argument, well known from Einstein's (1916, p.117) review of his general theory of relativity, amounts to a defense of Leibniz equivalence. He urges that the physical content of a theory is exhausted by the catalog of the spacetime coincidences it licenses. For example, in a theory that treats particles only, the coincidences are the points of intersection of the particle worldlines. These coincidences are preserved by transformations of the fields. Therefore two systems of fields that can be intertransformed have the same physical content; they represent the same physical system.

Over the years, the hole argument was deemed to be a trivial error by an otherwise insightful Einstein. It was John Stachel (1980) who recognized its highly non-trivial character and brought this realization to the modern community of historians and philosophers of physics. (See also Stachel, 1986.) In Earman and Norton (1987), the argument was recast as one that explicitly targets spacetime substantivalism. For further historical discussion, see Howard and Norton (1993), Janssen (forthcoming), Klein (1995) and Norton (1987).

9. Responses to the Hole Argument

There are at least as many responses to the hole argument as authors who have written on it. One line of thought simply agrees that the hole argument makes acceptance of Leibniz equivalence compelling. It seeks to make more transparent what that acceptance involves by trying to find a single mathematical structure that represents a physical spacetime system rather than the equivalence class of intertransformable structures licensed by Leibniz equivalence. One such attempt involves the notion of a "Leibniz algebra." (See Earman, 1989, Ch. 9, Sect. 9) It has become unclear that such attempts can succeed. Just as intertransformable fields represent the same physical system, there are distinct but intertransformable Leibniz algebras with the same physical import. If the formalisms of manifolds and of Leibniz algebras are intertranslatable, one would expect the hole argument to reappear in the latter formalism as well under this translation. (See Rynasiewicz, 1992.)

Einstein's original hole argument was formulated in the context of general relativity. The hole argument as formulated in Earman and Norton (1987) applies to all local spacetime theories and that includes generally covariant formulations of virtually all known spacetime theories. One view is that this goes too far, that general relativity is distinct from many other spacetime theories in that its spacetime geometry

has become dynamical and it is only in such theories that the hole argument should be mounted. (See Earman, 1989, Ch.9, Section 5; Stachel, 1993)

To critics, the hole argument presents a huge target. It consists of a series of assumptions all of which are needed to make good on its conclusion. The argument can be blocked by denying just one of its presumptions. Different authors have sought to sustain denial of virtually every one of them.

Perhaps the most promising of these attacks is one that requires the least modification of the ideas used to mount the hole argument. It is the proposal that spacetime is better represented not by the manifold of events alone but by some richer structure, such as the manifold of events in conjunction with metrical properties. (See, for example, Hoefer, 1996.) A slight and very popular variant allows that each event of the manifold represents a physical spacetime event, but which physical event that might be depends on the spreading of metric and matter fields on the manifold. Thus the indeterminism of the hole transformation can be eradicated since the metric and matter properties of an event can be carried with the transformation. (See, for example, Brighouse, 1994.)

More generally, we may well wonder whether the problems faced by spacetime substantivalism is an artifact of the particular formalism described above. Bain (1998) has explored the effect of a transition to other formalisms.

The simplest challenge notes that Leibniz equivalence is a standard presumption in the modern mathematical physics literature and suggests that even entertaining its denial (as manifold substantivalists must) is some kind of mathematical blunder unworthy of serious attention. While acceptance of Leibniz equivalence is widespread in the physics literature, it is not a logical truth that can only be denied on pain of contradiction. That it embodies non-trivial assumptions whose import must be accepted with sober reflection is indicated by the early acceptance of the hole argument by David Hilbert. If denial of Leibniz equivalence is a blunder so egregious that no competent mathematician would do it, then our standards for competence have become unattainably high, for they must exclude David Hilbert in 1915 at the height of his powers.

Another challenge seeks principled reasons for denying general covariance. One approach tries to establish that a spacetime can be properly represented by at most one of two intertransformable systems of fields on some manifold. So Maudlin (1990) urges that each spacetime event carries its metrical properties essentially, that is, it would not be that very event if (after redistribution of the fields) we tried to assign different metrical properties to it. Butterfield (1989) portrays intertransformable systems as different possible worlds and uses counterpart theory to argue that at most one can represent an actual spacetime.

These responses are just a few of a large range of responses of increasing ingenuity and technical depth. In the course of the scrutiny of the argument, virtually all its aspects have been weighed and tested. Is the indeterminism of the hole argument merely an artifact of an ill-chosen definition of determinism? Is the problem merely a trivial variant of the philosophical puzzle of inscrutability of reference? Or are there

deep matters of physics at issue? The debate continues over these and further issues. To enter it, the reader is directed to the bibliography below.

Notes to The Hole Argument

Notes

1. This one example illustrates the core content of the hole argument. With only a little further effort, the argument can be made more precise and general. This will be done concurrently in these notes, intended for readers with some background in differential geometry and general relativity. The form of the argument follows that originally laid out in Earman and Norton (1987). For a development of the hole argument at a technical level intermediate between the body of this article and these notes, see Norton (1992a, Section 5.12).

In general, the class of theories in which the hole argument is mounted are "local spacetime theories." These are theories whose models consist of n+1 tuples

$$(M, O_1, ..., O_n)$$

where the $O_1, ..., O_n$ are geometric object fields defined on a differential manifold M. The class of models in the theory is delimited by some set of invariant (e.g. tensorial) equations, which are the laws of the theory:

$$L_1=0, ..., L_m=0$$

where the quantities L_i are functions of the geometric objects O_i.The theory is presumed complete in the sense that any model satisfying these laws will be in the model set of the theory. This characterization of local spacetime theories is sufficiently general to include formulations of virtually all common spacetime theories, including general relativity, special relativity and Newtonian theories.

2. The distinction at issue here is between the passive and active reading of general covariance. Passive general covariance allows use of all coordinate charts of the differential manifold and is conferred automatically on theories formulated by modern methods. Active general covariance considers the dual point transformations induced by coordinate transformations. These amount to diffeomorphisms on the manifold M and the transformations of the fields correspond to maps that associate an object field O with its carry along h^*O under diffeomorphism h.

The need to convert Einstein's original analysis from passive to active transformations is awkward. I have argued that the distinction between them was not so clear cut when Einstein originally formulated the hole argument because of the more impoverished mathematical environment in which he worked and that this is responsible for much of the present confusion in interpreting Einstein's pronouncements on coordinate systems. See Norton (1989, 1992).

3. That is, a hole transformation is a diffeomorphism on M that is the identity outside some arbitrarily selected neighborhood but comes smoothly to differ from the identity within that neighborhood. For an explicit construction of such a transformation, see Muller (1995).

4. More generally, manifold substantivalism asserts that the manifold M of local spacetime theories is the mathematical structure that represents spacetime.

5. For any spacetime model $(M, O_1, ..., O_n)$ and any diffeomorphism on M, Leibniz equivalence asserts that the two models

$$(M, O_1, ..., O_n) \text{ and } (hM, h^*O_1, ..., h^*O_n)$$

represent the same physical system.

6. The general form of the argument is essentially identical. The first sentence is generalized to read:

> **1.** If one has two models of a local spacetime theory $(M, O_1, ..., O_n)$ and $(hM, h^*O_1, ..., h^*O_n)$ related by a hole transformation h, manifold substantivalists must maintain that the two systems represent two distinct physical systems.

Note also that statements 1 and 2 are premises. Statement 3 is the conclusion drawn from them. There is a suppressed premise that it is inadmissible to load up a physical theory with hidden properties that outstrip both observation and the determining power of the theory.

Time Travel and Modern Physics

Time travel has been a staple of science fiction. With the advent of general relativity it has been entertained by serious physicists. But, especially in the philosophy literature, there have been arguments that time travel is inherently paradoxical. The most famous paradox is the grandfather paradox: you travel back in time and kill your grandfather, thereby preventing your own existence. To avoid inconsistency some circumstance will have to occur which makes you fail in this attempt to kill your grandfather. Doesn't this require some implausible constraint on otherwise unrelated circumstances? We examine such worries in the context of modern physics.

A Botched Suicide

You are very depressed. You are suicidally depressed. You have a gun. But you do not quite have the courage to point the gun at yourself and kill yourself in this way. If only someone else would kill you, that would be a good thing. But you can't really ask someone to kill you. That wouldn't be fair. You decide that if you remain this depressed and you find a time machine, you will travel back in time to just about now, and kill your earlier self. That would be good. In that way you even would get rid of the depressing time you will spend between now and when you would get into that time machine. You start to muse about the coherence of this idea, when something amazing happens. Out of nowhere you suddenly see someone coming towards you with a gun pointed at you. In fact he looks very much like you, except that he is bleeding badly from his left eye, and can barely stand up straight. You are at peace. You look straight at him, calmly. He shoots. You feel a searing pain in your left eye. Your mind is in chaos, you stagger around and accidentally enter a strange looking cubicle. You drift off into unconsciousness. After a while, you can not tell how long, you drift back into consciousness and stagger out of the cubicle. You see someone in the distance looking at you calmly and fixedly. You realize that it is your younger self. He looks straight at you. You are in terrible pain. You have to end this, you have to kill him, really kill him once and for all. You shoot him, but your eyesight is so bad that your aim is off. You do not kill him, you merely damage his left eye. He staggers off. You fall to the ground in agony, and decide to study the paradoxes of time travel more seriously.

Why Do Time Travel Suicides Get Botched?

The standard worry about time travel is that it allows one to go back and kill one's younger self and thereby create paradox. More generally it allows for people or objects to travel back in time and to cause events in the past that are inconsistent with what in fact happened. (See e.g. Gödel 1949, Earman 1972, Malament 1985a&b, Horwich 1987.) A stone-walling response to this worry is that by logic indeed inconsistent events can not both happen. Thus in fact all such schemes to create paradox are logically bound to fail. So what's the worry?

Well, one worry is the question as to why such schemes always fail. Doesn't the necessity of such failures put *prima facie* unusual and unexpected constraints on the actions of people, or objects, that have traveled in time? Don't we have good reason to believe that there are no such constraints (in our world) and thus that there is no time travel (in our world)? We will later return to the issue of the palatability of such constraints, but first we want to discuss an argument that no constraints are imposed by time travel.

Topology and Constraints

Wheeler and Feynman (1949) were the first to claim that the fact that nature is continuous could be used to argue that causal influences from later events to earlier events, as are made possible by time travel, will not lead to paradox without the need for any constraints. Maudlin (1990) showed how to make their argument precise and more general, and argued that nonetheless it was not completely general.

Imagine the following set-up. We start off having a camera with a black and white film ready to take a picture of whatever comes out of the time machine. An object, in fact a developed film, comes out of the time machine. We photograph it, and develop the film. The developed film is subsequently put in the time machine, and set to come out of the time machine at the time the picture is taken. This surely will create a paradox: the developed film will have the opposite distribution of black, white, and shades of gray, from the object that comes out of the time machine. For developed black and white films (i.e. negatives) have the opposite shades of gray from the objects they are pictures of. But since the object that comes out of the time machine is the developed film itself it we surely have a paradox.

However, it does not take much thought to realize that there is no paradox here. What will happen is that a uniformly gray picture will emerge, which produces a developed film that has exactly the same uniform shade of gray. No matter what the sensitivity of the film is, as long as the dependence of the brightness of the developed film depends in a continuous manner on the brightness of the object being photographed, there will be a shade of gray that, when photographed, will produce exactly the same shade of gray on the developed film. This is the essence of Wheeler and Feynman's idea. Let us first be a bit more precise and then a bit more general.

For simplicity let us suppose that the film is always a uniform shade of gray (i.e. at any time the shade of gray does not vary by location on the film) The possible shades of gray of the film can then be represented by the (real) numbers from 0, representing pure black, to 1, representing pure white.

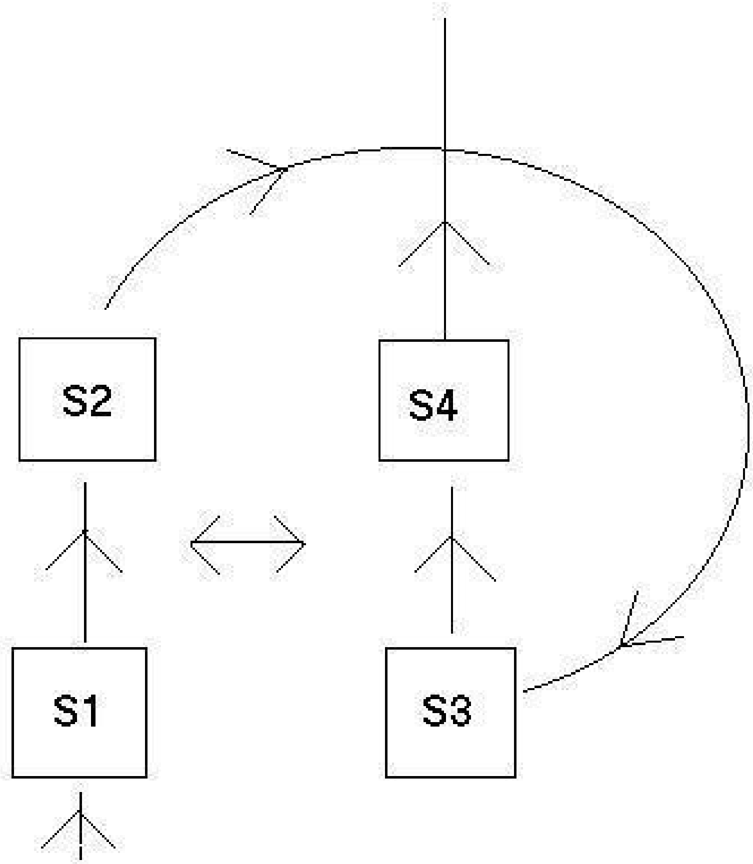

Figure 0

Let us now distinguish various stages in the chronogical order of the life of the film. In stage S_1 the film is young; it has just been placed in the camera and is ready to be exposed. It is then exposed to the object that comes out of the time machine. (That object in fact is a later stage of the film itself). By the time we come to stage S_2 of the life of the film, it has been developed and is about to enter the time machine. Stage S_3 occurs just after it exits the time machine and just before it is photographed. Stage S_4 occurs after it has been photographed and before it starts fading away. Let us assume that the film starts out in stage S_1 in some uniform shade of gray, and that the only significant change in the shade of gray of the film occurs between stages S_1 and S_2. During that period it acquires a shade of gray that depends on the shade of gray of the object that was photographed. I.e. the shade of gray that the film acquires at stage S_2 depends on the shade of gray it has at stage S_3. The influence of the shade of gray of the film at stage S_3, on the shade of gray of the film at stage S_2, can be represented as a mapping, or function, from the real numbers between 0 and 1 (inclusive), to the real numbers between 0 and 1 (inclusive). Let us suppose that the process of photography is such that if one imagines varying the shade of gray of an object in a smooth, continuous manner then the shade of gray of the developed picture of that object will also vary in a smooth, continuous manner. This implies that the function in question will be a continuous function. Now any continuous function from the real numbers between 0 and 1 (inclusive) to the real numbers between 0 and 1 (inclusive) must map at least one number to itself. One can quickly convince oneself of this by graphing such functions. For one will quickly see that any continuous function f from [0,1] to [0,1] must intersect the line x=y somewhere, and thus there must be at least one point

x such that f(x)=x. Such points are called fixed points of the function. Now let us think about what such a fixed point represents. It represents a shade of gray such that, when photographed, it will produce a developed film with exactly that same shade of gray. The existence of such a fixed point implies a solution to the apparent paradox.

Let us now be more general and allow color photography. One can represent each possible color of an object (of uniform color) by the proportions of blue, green and red that make up that color. (This is why television screens can produce all possible colors.) Thus one can represent all possible colors of an object by three points on three orthogonal lines x, y and z, that is to say, by a point in a three-dimensional cube. This cube is also known as the 'Cartesian product' of the three line segments. Now, one can also show that any continuous map from such a cube to itself must have at least one fixed point. So color photography can not be used to create time travel paradoxes either!

Even more generally, consider some system *P* which, as in the above example, has the following life. It starts in some state S_1, it interacts with an object that comes out of a time machine (which happens to be its older self), it travels back in time, it interacts with some object (which happens to be its younger self), and finally it grows old and dies. Let us assume that the set of possible states of *P* can be represented by a Cartesian product of *n* closed intervals of the reals, i.e. let us assume that the topology of the state-space of *P* is isomorphic to a finite Cartesian product of closed intervals of the reals. Let us further assume that the development of *P* in time, and the dependence of that development on the state of objects that it interacts with, is continuous. Then, by a well-known fixed point theorem in topology (see e.g. Hocking and Young 1961, p 273), no matter what the nature of the interaction is, and no matter what the initial state of the object is, there will be at least one state S_3 of the older system (as it emerges from the time travel machine) that will influence the initial state S_1 of the younger system (when it encounters the older system) so that, as the younger system becomes older, it develops exactly into state S_3. Thus without imposing any constraints on the initial state S_1 of the system *P*, we have shown that there will always be perfectly ordinary, non-paradoxical, solutions, in which everything that happens, happens according to the usual laws of development. Of course, there is looped causation, hence presumably also looped explanation, but what do you expect if there is looped time?

Unfortunately, for the fan of time travel, a little reflection suggests that there are systems for which the needed fixed point theorem does not hold. Imagine, for instance, that we have a dial that can only rotate in a plane. We are going to put the dial in the time machine. Indeed we have decided that if we see the later stage of the dial come out of the time machine set at angle *x*, then we will set the dial to *x*+90, and throw it into the time machine. Now it seems we have a paradox, since the mapping that consists of a rotation of all points in a circular state-space by 90 degrees does not have a fixed point. And why wouldn't some state-spaces have the topology of a circle?

However, we have so far not used another continuity assumption which is also a reasonable assumption. So far we have only made the following demand: the state the dial is in at stage S_2 must be a continuous function of the state of the dial at stage S_3. But, the state of the dial at stage S_2 is arrived at by taking the state of the dial at stage S_1, and rotating it over some angle. It is not merely the case that the effect of the interaction, namely the state of the dial at stage S_2, should be a continuous function of the cause, namely the state of the dial at stage S_3. It is additionally the case that path taken to get there, the way the dial is rotated between stages S_1 and S_2 must be a continuous function of the state at stage S_3. And, rather surprisingly, it turns out that this can not be done. Let us illustrate what the problem is before going to a more general demonstration that there must be a fixed point solution in the dial case.

Forget time travel for the moment. Suppose that you and I each have a watch with a single dial neither of which is running. My watch is set at 12. You are going to announce what your watch is set at. My task is going to be to adjust my watch to yours no matter what announcement you make. And my actions should have a continuous (single valued) dependence on the time that you announce. Surprisingly, this is not possible! For instance, suppose that if you announce "12", then I achieve that setting on my watch by doing nothing. Now imagine slowly and continuously increasing the announced times, starting at 12. By continuity, I must achieve each of those settings by rotating my dial to the right. If at some point I switch and achieve the announced goal by a rotation of my dial to the left, I will have introduced a discontinuity in my actions, a

discontinuity in the actions that I take as a function of the announced angle. So I will be forced, by continuity, to achieve every announcement by rotating the dial to the right. But, this rotation to the right will have to be abruptly discontinued as the announcements grow larger and I eventually approach 12 again, since I achieved 12 by not rotating the dial at all. So, there will be a discontinuity at 12 at the latest. In general, continuity of my actions as a function of announced times can not be maintained throughout if I am to be able to replicate all possible settings. Another way to see the problem is that one can similarly reason that, as one starts with 12, and imagines continuously making the announced times earlier, one will be forced, by continuity, to achieve the announced times by rotating the dial to the left. But the conclusions drawn from the assumption of continuous increases and the assumption of continuous decreases are inconsistent. So we have an inconsistency following from the assumption of continuity and the assumption that I always manage to set my watch to your watch. So, a dial developing according to a continuous dynamics from a given initial state, can not be set up so as to react to a second dial, with which it interacts, in such a way that it is guaranteed to always end up set at the same angle as the second dial. Similarly, it can not be set up so that it is guaranteed to always end up set at 90 degrees to the setting of the second dial. All of this has nothing to do with time travel. However, the impossibility of such set ups is what prevents us from enacting the rotation by 90 degrees that would create paradox in the time travel setting.

Let us now give the positive result that with such dials there will always be fixed point solutions, as long as the dynamics is continuous. Let us call the state of the dial before it interacts with its older self the initial state of the dial. And let us call the state of the dial after it emerges from the time machine the final state of the dial. We can represent the possible initial and final states of the dial by the angles *x* and *y* that the dial can point at initially and finally. The set of possible initial plus final states thus forms a torus. (See figure 1.)

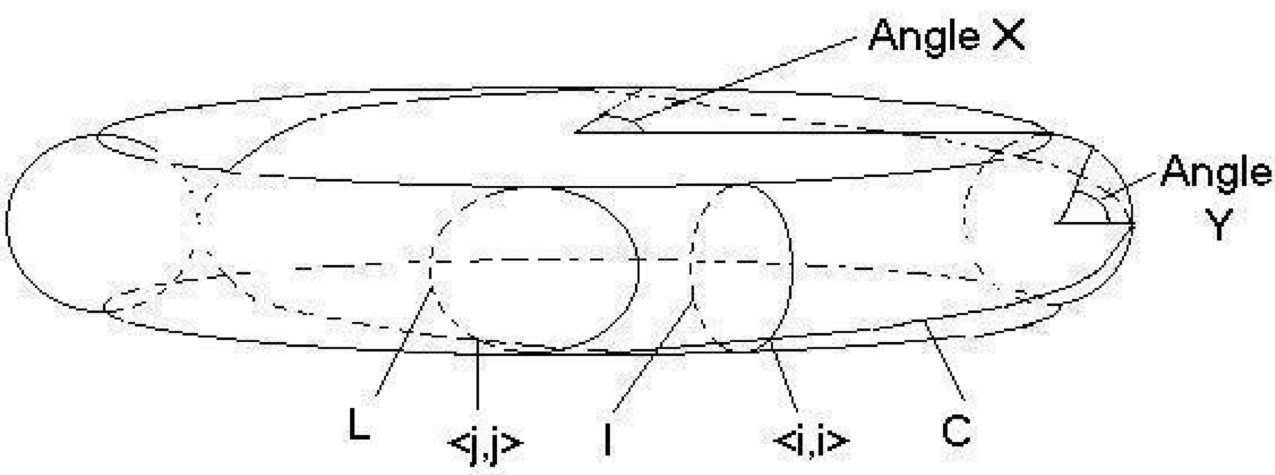

Figure 1

Suppose that the dial starts at angle *I*. The initial angle *I* that the dial is at before it encounters its older self, and the set of all possible final angles that the dial can have when it emerges from the time machine is represented by the circle *I* on the torus

(see figure 1). Given any possible angle of the emerging dial the dial initially at angle *I* will develop to some other angle. One can picture this development by rotating each point on *I* in the horizontal direction by the relevant amount. Since the rotation has to depend continuously on the angle of the emerging dial, ring *I* during this development will deform into some loop *L* on the torus. Loop *L* thus represents the angle *x* that the dial is at when it is thrown into the time machine, given that it started at angle *I* and then encountered a dial (its older self) which was at angle *y* when it emerged from the time machine. We therefore have consistency if *x*=*y* for some *x* and *y* on loop *L*. Now, let loop *C* be the loop which consists of all the points on the torus for which *x*=*y*. Ring *I* intersects *C* at point <*i*,*i*>. Obviously any continuous deformation of *I* must still intersect *C* somewhere. So *L* must intersect *C* somewhere, say at <*j*,*j*>. But that means that no matter how the development of the dial starting at *I* depends on the angle of the emerging dial, there will be some angle for the emerging dial such that the dial will develop exactly into that angle (by the time it enters the time machine) under the influence of that emerging dial. This is so no matter what angle one starts with, and no matter how the development depends on the angle of the emerging dial. Thus even for a circular state-space there are no constraints needed other than continuity.

Unfortunately there are state-spaces that escape even this argument. Consider for instance a pointer that can be set to all values between 0 and 1, where 0 and 1 are not possible values. I.e. suppose that we have a state-space that is isomorphic to an open set of real numbers. Now suppose that we have a machine that sets the pointer to half the value that the pointer is set at when it emerges from the time machine.

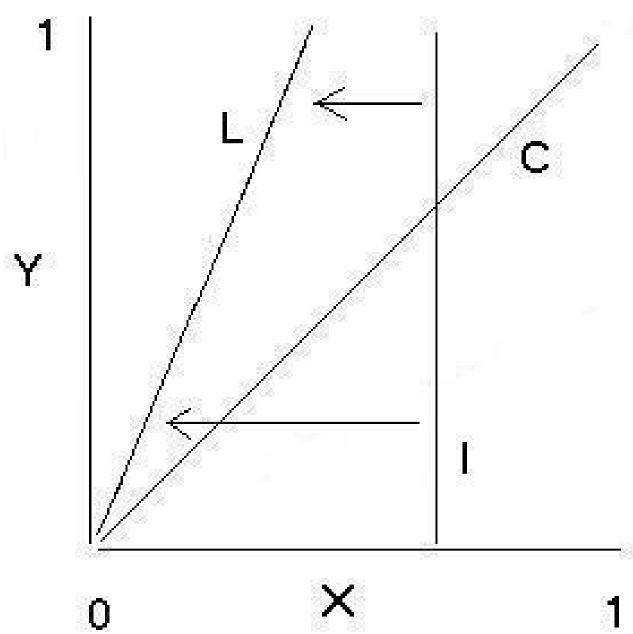

Figure 2

Suppose the pointer starts at value *I*. As before we can represent the combination of this initial position and all possible final positions by the line *I*. Under the influence of the pointer coming out of the time machine the pointer value will develop to a value that equals half the value of the final value that it encountered. We can represent this development as the continuous deformation of line *I* into line *L*, which is indicated by the arrows in Figure 2. This development is fully continuous. Points <*x*,*y*> on line *I* represent the initial position *x*=*I* of the (young) pointer, and the position y of the older pointer as it emerges

from the time machine. Points <*x,y*> on line *L* represent the position x that the younger pointer should develop into, given that it encountered the older pointer emerging from the time machine set at position y. Since the pointer is designed to develop to half the value of the pointer that it encounters, the line *L* corresponds to $x=1/2y$. We have consistency if there is some point such that it develops into that point, if it encounters that point. Thus, we have consistency if there is some point <*x,y*> on line *L* such that $x=y$. However, there is no such point: lines *L* and *C* do not intersect. Thus there is no consistent solution, despite the fact that the dynamics is fully continuous.

Of course if 0 were a possible value *L* and *C* would intersect at 0. This is surprising and strange: adding one point to the set of possible values of a quantity here makes the difference between paradox and peace. One might be tempted to just add the extra point to the state-space in order to avoid problems. After all, one might say, surely no measurements could ever tell us whether the set of possible values includes that exact point or not. Unfortunately there can be good theoretical reasons for supposing that some quantity has a state-space that is open: the set of all possible speeds of massive objects in special relativity surely is an open set, since it includes all speeds up to, but not including, the speed of light. Quantities that have possible values that are not bounded also lead to counter examples to the presented fixed point argument. And it is not obvious to us why one should exclude such possibilities. So the argument that no constraints are needed is not fully general.

An interesting question of course is: exactly for which state-spaces must there be such fixed points. We do not know the general answer.

The General Possibility of Time Travel in General Relativity

Time travel has recently been discussed quite extensively in the context of general relativity. Time travel can occur in general relativistic models in which one has closed time-like curves (CTC's). A time like curve is simply a space-time trajectory such that the speed of light is never equalled or exceeded along this trajectory. Time-like curves thus represent the possible trajectories of ordinary objects. If there were time-like curves which were closed (formed a loop), then travelling along such a curve one would never exceed the speed of light, and yet after a certain amount of (proper) time one would return to a point in space-time that one previously visited. Or, by staying close to such a CTC, one could come arbitrarily close to a point in space-time that one previously visited. General relativity, in a straightforward sense, allows time travel: there appear to be many space-times compatible with the fundamental equations of General Relativity in which there are CTC's. Space-time, for instance, could have a Minkowski metric everywhere, and yet have CTC's everywhere by having the temporal dimension (topologically) rolled up as a circle. Or, one can have wormhole connections between different parts of space-time which allow one to enter ‘mouth *A*’ of such a wormhole connection, travel through the wormhole, exit the wormhole at ‘mouth *B*’ and re-enter ‘mouth *A*’ again. Or, one can have space-times which topologically are R4, and yet have CTC's due to the ‘tilting’ of light cones (Gödel space-times, Taub-NUT space-times, etc.)

General relativity thus appears to provide ample opportunity for time travel. Note that just because there are CTC's in a space-time, this does not mean that one can get from any point in the space-time to any other point by following some future directed timelike curve. In many space-times in which there are CTC's such CTC's do not occur all over space-time. Some parts of space-time can have CTC's while other parts do not. Let us call the part of a space-time that has CTC's the "time travel region" of that space-time, while calling the rest of that space-time the "normal region". More precisely, the "time travel region" consists of all the space-time points *p* such that there exists a (non-zero length) timelike curve that starts at *p* and returns to *p*. Now let us start examining space-times with CTC's a bit more closely for potential problems.

Two Toy Models

In order to get a feeling for the sorts of implications that closed timelike curves can have, it may be useful to consider two simple models. In space-times with closed timelike curves the traditional initial value problem cannot be framed in the usual way. For it presupposes the existence of Cauchy surfaces, and if there are CTCs then no Cauchy surface exists. (A Cauchy surface is a spacelike surface such that every inextendible timelike curve crosses it exactly once. One normally specifies

initial conditions by giving the conditions on such a surface.) Nonetheless, if the topological complexities of the manifold are appropriately localized, we can come quite close. Let us call an edgeless spacelike surface *S* a *quasi-Cauchy* surface if it divides the rest of the manifold into two parts such that a) every point in the manifold can be connected by a timelike curve to *S*, and b) any timelike curve which connects a point in one region to a point in the other region intersects *S* exactly once. It is obvious that a quasi-Cauchy surface must entirely inhabit the normal region of the space-time; if any point *p* of *S* is in the time travel region, then any timelike curve which intersects *p* can be extended to a timelike curve which intersects *S* near *p* again. In extreme cases of time travel, a model may have no normal region at all (e.g. Minkowski space-time rolled up like a cylinder in a time-like direction), in which case our usual notions of temporal precedence will not apply. But temporal anomalies like wormholes (and time machines) can be sufficiently localized to permit the existence of quasi-Cauchy surfaces.

Given a timelike orientation, a quasi-Cauchy surface unproblematically divides the manifold into its *past* (i.e. all points that can be reached by past-directed timelike curves from *S*) and its *future* (ditto *mutatis mutandis*). If the whole past of *S* is in the normal region of the manifold, then *S* is a *partial Cauchy surface*: every inextendible timelike curve which exists to the past of *S* intersects *S* exactly once, but (if there is time travel in the future) not every inextendible timelike curve which exists to the future of *S* intersects *S*. Now we can ask a particularly clear question: consider a manifold which contains a time travel region, but also has a partial Cauchy surface *S*, such that all of the temporal funny business is to the future of *S*. If all you could see were *S* and its past, you would not know that the space-time had any time travel at all. The question is: are there any constraints on the sort of data which can be put on *S* and continued to a global solution of the dynamics which are different from the constraints (if any) on the data which can be put on a Cauchy surface in a simply connected manifold and continued to a global solution? If there is time travel to our future, might we we able to tell this now, because of some implied oddity in the arrangement of present things?

It is not at all surprising that there might be constraints on the data which can be put on a locally space-like surface which passes through the time travel region: after all, we never think we can freely specify what happens on a space-like surface and on another such surface to its future, but in this case the surface at issue lies to its own future. But if there were particular constraints for data on a partial Cauchy surface then we would apparently need to have to rule out some sorts of otherwise acceptable states on *S* if there is to be time travel to the future of *S*. We then might be able to establish that there will be no time travel in the future by simple inspection of the present state of the universe. As we will see, there is reason to suspect that such constraints on the partial Cauchy surface are non-generic. But we are getting ahead of ourselves: first let's consider the effect of time travel on a very simple dynamics.

The simplest possible example is the Newtonian theory of perfectly elastic collisions among equally massive particles in one spatial dimension. The space-time is two-dimensional, so we can represent it initially as the Euclidean plane, and the dynamics is completely specified by two conditions. When particles are traveling freely, their world lines are straight lines in the space-time, and when two particles collide, they exchange momenta, so the collision looks like an 'X' in space-time, with each particle changing its momentum at the impact.[1] The dynamics is purely local, in that one can check that a set of world-lines constitutes a model of the dynamics by checking that the dynamics is obeyed in every arbitrarily small region. It is also trivial to generate solutions from arbitrary initial data if there are no CTCs: given the initial positions and momenta of a set of particles, one simply draws a straight line from each particle in the appropriate direction and continues it indefinitely. Once all the lines are drawn, the worldline of each particle can be traced from collision to collision. The boundary value problem for this dynamics is obviously well-posed: any set of data at an instant yields a unique global solution, constructed by the method sketched above.

What happens if we change the topology of the space-time by hand to produce CTCs? The simplest way to do this is depicted in figure 3: we cut and paste the space-time so it is no longer simply connected by identifying the line $L-$ with the line $L+$. Particles "going in" to $L+$ from below "emerge" from $L-$, and particles "going in" to $L-$ from below "emerge" from $L+$.

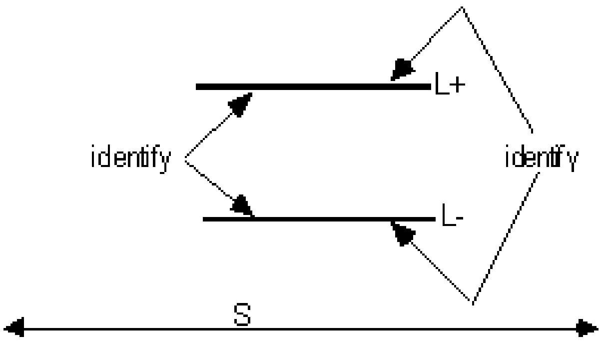

Figure 3: Inserting CTCs by Cut and Paste

How is the boundary-value problem changed by this alteration in the space-time? Before the cut and paste, we can put arbitrary data on the simultaneity slice *S* and continue it to a unique solution. After the change in topology, *S* is no longer a Cauchy surface, since a CTC will never intersect it, but it is a partial Cauchy surface. So we can ask two questions. First, can arbitrary data on *S* always be continued to a global solution? Second, is that solution unique? If the answer to the first question is *no*, then we have a backward-temporal constraint: the existence of the region with CTCs places constraints on what can happen on *S* even though that region lies completely to the future of *S*. If the answer to the second question is *no*, then we have an odd sort of indeterminism: the complete physical state on *S* does not determine the physical state in the future, even though the local dynamics is perfectly deterministic and even though there is no other past edge to the space-time region in *S*'s future (i.e. there is nowhere *else* for boundary values to come from which could influence the state of the region).

In this case the answer to the first question is *yes* and to the second is *no*: there are no constraints on the data which can be put on *S*, but those data are always consistent with an infinitude of different global solutions. The easy way to see that there always is a solution is to construct the minimal solution in the following way. Start drawing straight lines from *S* as required by the initial data. If a line hits *L*— from the bottom, just continue it coming out of the top of *L*+ in the appropriate place, and if a line hits *L*+ from the bottom, continue it emerging from *L*— at the appropriate place. Figure 4 represents the minimal solution for a single particle which enters the time-travel region from the left:

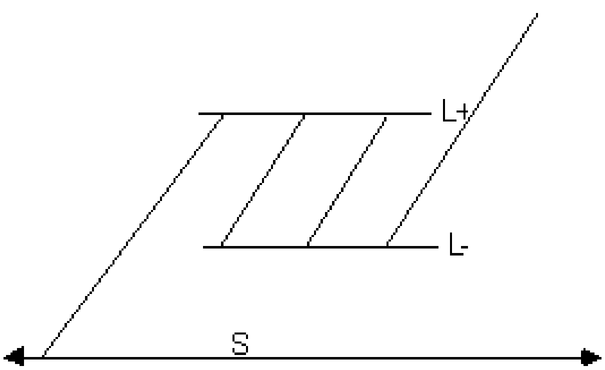

Figure 4: The Minimal Solution

The particle ‘travels back in time’ three times. It is obvious that this minimal solution is a global solution, since the particle always travels inertially.

But the same initial state on *S* is also consistent with other global solutions. The new requirement imposed by the topology is just that the data going into *L*+ from the bottom match the data coming out of *L*— from the top, and the data going into *L*- from the bottom match the data coming out of *L*+ from the top. So we can add any number of vertical lines connecting *L*- and *L*+ to a solution and still have a solution. For example, adding a few such lines to the minimal solution yields:

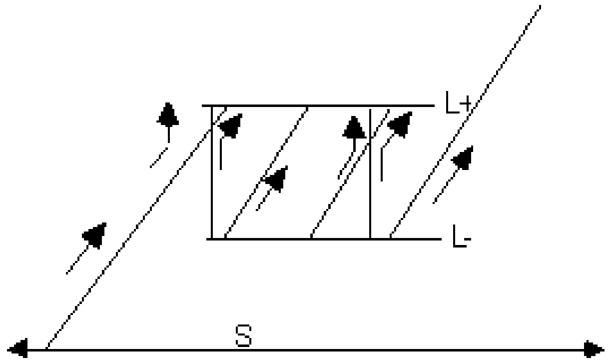

Figure 5: A Non-Minimal Solution

The particle now collides with itself twice: first before it reaches *L*+ for the first time, and again shortly before it exits the CTC region. From the particle's point of view, it is traveling to the right at a constant speed until it hits an older version of itself and comes to rest. It remains at rest until it is hit from the right by a younger version of itself, and then continues moving off, and the same process repeats later. It is clear that this is a global model of the dynamics, and that any number of distinct models could be generating by varying the number and placement of vertical lines.

Knowing the data on *S*, then, gives us only incomplete information about how things will go for the particle. We know that the particle will enter the CTC region, and will reach *L*+, we know that it will be the only particle in the universe, we know exactly where and with what speed it will exit the CTC region. But we cannot determine how many collisions the particle will undergo (if any), nor how long (in proper time) it will stay in the CTC region. If the particle were a clock, we could not predict what time it would indicate when exiting the region. Furthermore, the dynamics gives us no handle on what to think of the various possibilities: there are no probabilities assigned to the various distinct possible outcomes.

Changing the topology has changed the mathematics of the situation in two ways, which tend to pull in opposite directions. On the one hand, *S* is no longer a Cauchy surface, so it is perhaps not surprising that data on *S* do not suffice to fix a unique global solution. But on the other hand, there is an added constraint: data "coming out" of *L*− must exactly match data "going in" to *L*+, even though what comes out of *L*− helps to determine what goes into *L*+. This added consistency constraint tends to cut down on solutions, although in this case the additional constraint is more than outweighed by the freedom to consider various sorts of data on *L*+/*L*-.

The fact that the extra freedom outweighs the extra constraint also points up one unexpected way that the supposed paradoxes of time travel may be overcome. Let's try to set up a paradoxical situation using the little closed time loop above. If we send a single particle into the loop from the left and do nothing else, we know exactly where it will exit the right side of the time travel region. Now suppose we station someone at the other side of the region with the following charge: if the particle should come out on the right side, the person is to do something to *prevent* the particle from going in on the left in the first place. In fact, this is quite easy to do: if we send a particle in from the right, it seems that it can exit on the left and *deflect* the incoming left-hand particle.

Carrying on our reflection in this way, we further realize that if the particle comes out on the right, we might as well send *it* back in order to deflect itself from entering in the first place. So all we really need to do is the following: set up a perfectly reflecting particle mirror on the right-hand side of the time travel region, and launch the particle from the left so that--*if nothing interferes with it*--it will just barely hit *L*+. Our paradox is now apparently complete. If, on the one hand, nothing interferes with the particle it will enter the time-travel region on the left, exit on the right, be reflected from the mirror, re-enter from the right, and come out on the left to prevent itself from ever entering. So if it enters, it gets deflected and never enters. On the other hand, if it never enters then nothing goes in on the left, so nothing comes out on the right, so nothing is reflected back, and there is nothing to deflect it from entering. So if it doesn't enter, then there is nothing to deflect it and it enters. If it enters, then it is deflected and doesn't enter; if it doesn't enter then there is nothing to deflect it and it enters: paradox complete.

But at least one solution to the supposed paradox is easy to construct: just follow the recipe for constructing the minimal solution, continuing the initial trajectory of the particle (reflecting it the mirror in the obvious way) and then read of the number and trajectories of the particles from the resulting diagram. We get the result of figure 6:

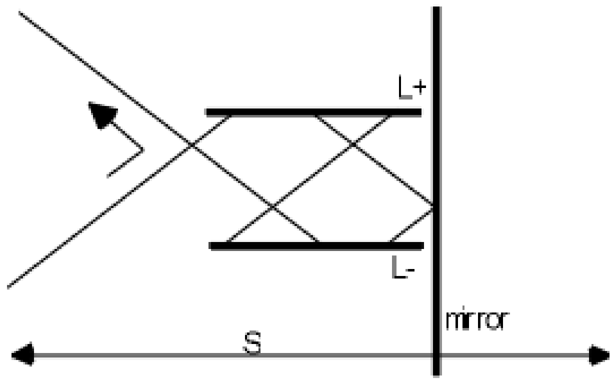

Figure 6: Resolving the "Paradox"

As we can see, the particle approaching from the left never reaches *L*+: it is deflected first by a particle which emerges from *L*-. But it is not deflected *by itself*, as the paradox suggests, it is deflected by another particle. Indeed, there are now *four* particles in the diagram: the original particle and three particles which are confined to closed time-like curves. It is not the leftmost particle which is reflected by the mirror, nor even the particle which deflects the leftmost particle; it is another particle altogether.

The paradox gets it traction from an incorrect presupposition: if there is only one particle in the world at *S* then there is only one particle which could participate in an interaction in the time travel region: the single particle would have to interact with its earlier (or later) self. But there is no telling what might come out of $L-$: the only requirement is that whatever comes out must match what goes in at *L*+. So if you go to the trouble of constructing a working time machine, you should be prepared for a different kind of disappointment when you attempt to go back and kill yourself: you may be prevented from entering the machine in the first place by some completely unpredictable entity which emerges from it. And once again a peculiar sort of indeterminism appears: if there are many self-consistent things which could prevent you from entering, there is no telling which is even likely to materialize.

So when the freedom to put data on $L-$ outweighs the constraint that the same data go into *L*+, instead of paradox we get an embarrassment of riches: many solution consistent with the data on *S*. To see a case where the constraint "outweighs" the freedom, we need to construct a very particular, and frankly artificial, dynamics and topology. Consider the space of all linear dynamics for a scalar field on a lattice. (The lattice can be though of as a simple discrete space-time.) We will depict the space-time lattice as a directed graph. There is to be a scalar field defined at every node of the graph, whose value at a given node depends linearly on the values of the field at nodes which have arrows which lead to it. Each edge of the graph can be assigned a weighting factor which determines how much the field at the input node contributes to the field at the output node. If we name the nodes by the letters *a*, *b*, *c*, etc., and the edges by their endpoints in the obvious way, then we can label the weighting factors by the edges they are associated with in an equally obvious way.

Suppose that the graph of the space-time lattice is *acyclic*, as in figure 7. (A graph is *Acyclic* if one can not travel in the direction of the arrows and go in a loop.)

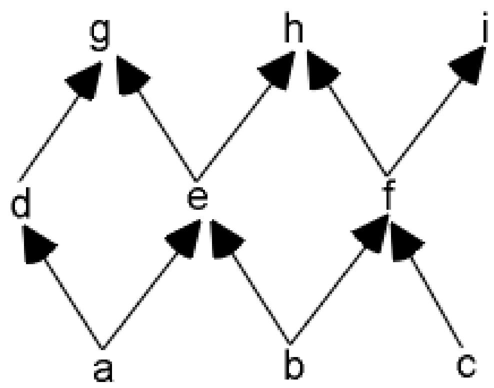

Figure 7: An Acyclic Lattice

It is easy to regard a set of nodes as the analog of a Cauchy surface, e.g. the set {*a*, *b*, *c*}, and it is obvious if arbitrary data are put on those nodes the data will generate a unique solution in the future.[2] If the value of the field at node *a* is 3 and at node *b* is 7, then its value at node *d* will be $3W_{ad}$ and its value at node *e* will be $3W_{ae} + 7W_{be}$. By varying the weighting factors we can adjust the dynamics, but in an acyclic graph the future evolution of the field will always be unique.

Let us now again artificially alter the topology of the lattice to admit CTCs, so that the graph now is cyclic. One of the simplest such graphs is depicted in figure 8: there are now paths which lead from *z* back to itself, e.g. *z* to *y* to *z*.

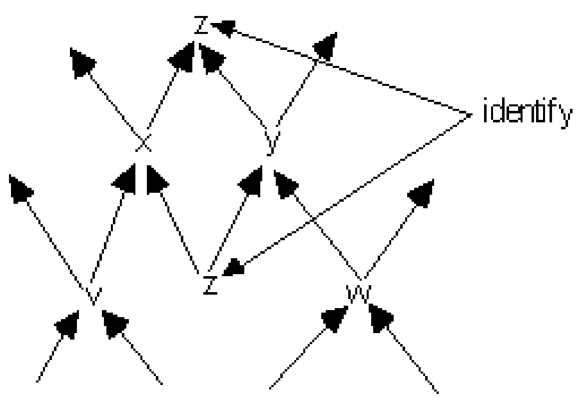

Figure 8: Time Travel on a Lattice

Can we now put arbitrary data on *v* and *w*, and continue that data to a global solution? Will the solution be unique?

In the generic case, there will be a solution and the solution will be unique. The equations for the value of the field at *x*, *y*, and *z* are:

$$x = vW_{vx} + zW_{zx}$$
$$y = wW_{wy} + zW_{zy}$$
$$z = xW_{xz} + yW_{yz}.$$

Solving these equations for *z* yields

$$z = (vW_{vx} + zW_{zx})W_{xz} + (wW_{wy} + zW_{zy})W_{yz},$$

or

$$z = (vW_{vx}W_{xz} + wW_{wy}W_{yz})/\ (1 - W_{zx}W_{xz} - W_{zy}W_{yz}),$$

which gives a unique value for z in the generic case. But looking at the space of all possible dynamics for this lattice (i.e. the space of all possible weighting factors), we find a singularity in the case where $1 - W_{zx}W_{xz} - W_{zy}W_{yz} = 0$. If we choose weighting factors in just this way, then arbitrary data at *v* and *w* cannot be continued to a global solution. Indeed, if the scalar field is everywhere non-negative, then this particular choice of dynamics puts ironclad constraints on the value of the field at *v* and *w*: the field there must be zero (assuming W_{vx} and W_{wy} to be non-zero), and similarly all nodes in their past must have field value zero. If the field can take negative values, then the values at *v* and *w* must be so chosen that $vW_{vx}W_{xz} = -wW_{wy}W_{yz}$. In either case, the field values at *v* and *w* are severely constrained by the existence of the CTC region even though these nodes lie completely to the past of that region. It is this sort of constraint which we find to be unlike anything which appears in standard physics.

Our toy models suggest three things. The first is that it may be impossible to prove in complete generality that arbitrary data on a partial Cauchy surface can *always* be continued to a global solution: our artificial case provides an example where it cannot. The second is that such odd constraints are not likely to be generic: we had to delicately fine-tune the dynamics to get a problem. The third is that the opposite problem, namely data on a partial Cauchy surface being consistent with *many* different global solutions, is likely to be generic: we did not have to do any fine-tuning to get this result. And this leads to a peculiar sort of indeterminism: the entire state on *S* does not determine what will happen in the future even though the local dynamics is deterministic and there are no other "edges" to space-time from which data could influence the result. What happens in the time travel region is constrained but not determined by what happens on *S*, and the dynamics does not even supply any *probabilities* for the various possibilities. The example of the photographic negative discussed in section 3, then, seems likely to be unusual, for in that case there is a *unique* fixed point for the dynamics, and the set-up plus the dynamical laws *determine* the outcome. In the generic case one would rather expect *multiple* fixed points, with no room for anything to influence, even probabilistically, *which* would be realized.

It is ironic that time travel should lead generically not to contradictions or to constraints (in the normal region) but to *underdetermination* of what happens in the time travel region by what happens everywhere else (an underdetermination tied neither to a probabilistic dynamics or to a free edge to space-time). The traditional objection to time travel is that it leads to contradictions: there is no consistent way to complete an arbitrarily constructed story about how the time traveler intends to act. Instead, though, it appears that the problem is underdetermination: the story can be consistently completed in many different ways. Let us now discuss some results regarding some slightly more realistic models that have been discussed in the physics literature.

Slightly More Realistic Models of Time Travel

Echeverria, Klinkhammer and Thorne (1991) considered the case of 3-dimensional single hard spherical ball that can go through a single time travel wormhole so as to collide with its younger self.

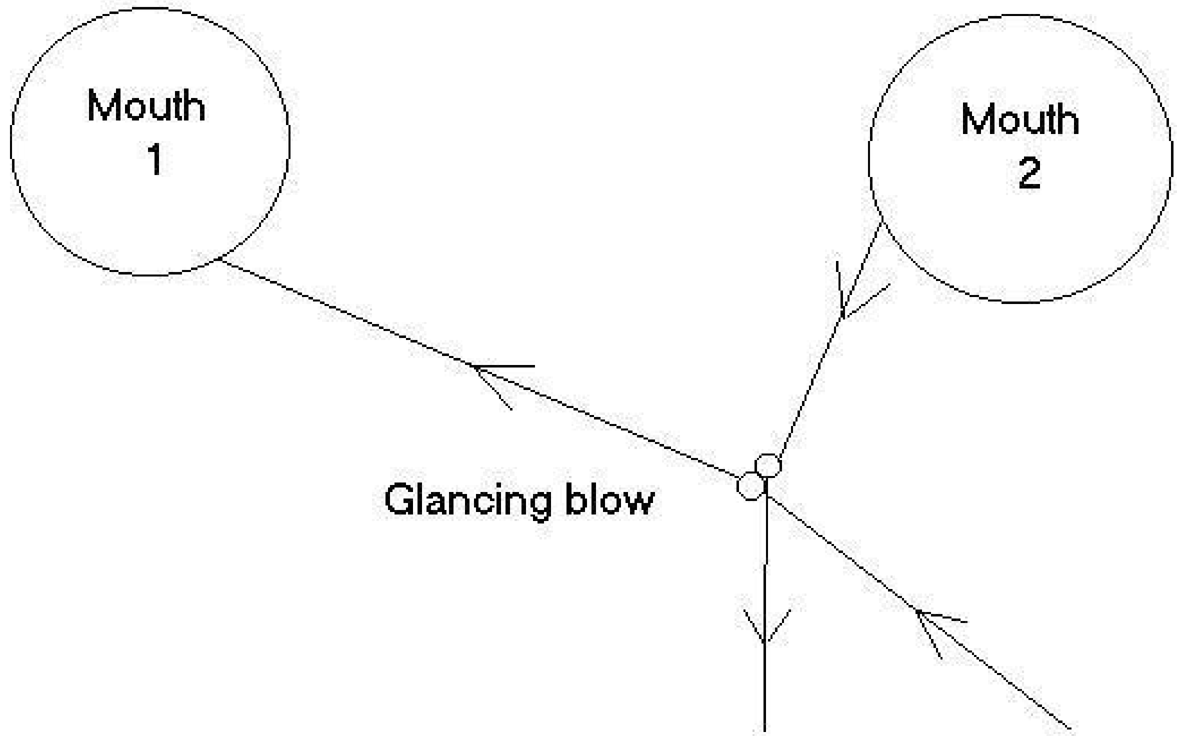

Figure 9

The threat of paradox in this case arises in the following form. There are initial trajectories (starting in the non-time travel region of space-time) for the ball such that if such a trajectory is continued (into the time travel region), assuming that the ball does not undergo a collision prior to entering mouth 1 of the wormhole, it will exit mouth 2 so as to collide with its earlier self prior to its entry into mouth 1 in such a way as to prevent its earlier self from entering mouth 1. Thus it seems that the ball will enter mouth 1 if and only if it does not enter mouth 1. Of course, the Wheeler-Feynman strategy is to look for a 'glancing blow' solution: a collision which will produce exactly the (small) deviation in trajectory of the earlier ball that produces exactly that collision. Are there always such solutions?[3]

Echeverria, Klinkhammer & Thorne found a large class of initial trajectories that have consistent 'glancing blow' continuations, and found none that do not (but their search was not completely general). They did not produce a rigorous proof that every initial trajectory has a consistent continuation, but suggested that it is very plausible that every initial trajectory has a consistent continuation. That is to say, they have made it very plausible that, in the billiard ball wormhole case, the time travel structure of such a wormhole space-time does not result in constraints on states on spacelike surfaces in the non-time travel region.

In fact, as one might expect from our discussion in the previous section, they found the opposite problem from that of inconsistency: they found underdetermination. For a large class of initial trajectories there are multiple different consistent 'glancing blow' continuations of that trajectory (many of which involve multiple wormhole traversals). For example, if one initially has a ball that is traveling on a trajectory aimed straight between the two mouths, then one obvious solution is that the ball passes between the two mouths and never time travels. But another solution is that the younger ball gets knocked into mouth 1 exactly so as to come out of mouth 2 and produce that collision. Echeverria et al. do not note the possibility (which we pointed out in the previous section) of the existence of additional balls in the time travel region. We conjecture (but have no proof) that for every initial trajectory of A there are some, and generically many, multiple ball continuations.

Friedman et al. 1990 examined the case of source free non-self-interacting scalar fields traveling through such a time travel wormhole and found that no constraints on initial conditions in the non-time travel region are imposed by the existence of such time travel wormholes. In general there appear to be no known counter examples to the claim that in ‘somewhat realistic’ time-travel space-times with a partial Cauchy surface there are no constraints imposed on the state on such a partial Cauchy surface by the existence of CTC's. (See e.g. Friedman and Morris 1991, Thorne 1994, Earman 1995, Earman and Smeenk 1999.)

How about the issue of constraints in the time travel region *T*? *Prima facie*, constraints in such a region would not appear to be surprising. But one might still expect that there should be no constraints on states on a spacelike surface, provided one keeps the surface ‘small enough’. In the physics literature the following question has been asked: for any point *p* in *T*, and any space-like surface *S* that includes *p* is there a neighborhood *E* of *p* in *S* such that any solution on *E* can be extended to a solution on the whole space-time? With respect to this question, there are some simple models in which one has this kind of extendibility of local solutions to global ones, and some simple models in which one does not have such extendibility, with no clear general pattern. (See e.g. Yurtsever 1990, Friedman et. al. 1990, Novikov 1992, Earman 1995, Earman and Smeenk 1999). What are we to think of all of this?

Even If There are Constraints, So What?

Since it is not obvious that one can rid oneself of all constraints in realistic models, let us examine the argument that time travel is implausible, and we should think it unlikely to exist in our world, in so far as it implies such constraints. The argument goes something like the following. In order to satisfy such constraints one needs some pre-established divine harmony between the global (time travel) structure of space-time and the distribution of particles and fields on space-like surfaces in it. But it is not plausible that the actual world, or any world even remotely like ours, is constructed with divine harmony as part of the plan. In fact, one might argue, we have empirical evidence that conditions in any spatial region can vary quite arbitrarily. So we have evidence that such constraints, whatever they are, do not in fact exist in our world. So we have evidence that there are no closed time-like lines in our world or one remotely like it. We will now examine this argument in more detail by presenting four possible responses, with counterresponses, to this argument.

Response 1. There is nothing implausible or new about such constraints. For instance, if the universe is spatially closed, there has to be enough matter to produce the needed curvature, and this puts constraints on the matter distribution on a space-like hypersurface. Thus global space-time structure can quite unproblematically constrain matter distributions on space-like hypersurfaces in it. Moreover we have no realistic idea what these constraints look like, so we hardly can be said to have evidence that they do not obtain.

Counterresponse 1. Of course there are constraining relations between the global structure of space-time and the matter in it. The Einstein equations relate curvature of the manifold to the matter distribution in it. But what is so strange and implausible about the constraints imposed by the existence of closed time-like curves is that these constraints in essence have nothing to do with the Einstein equations. When investigating such constraints one typically treats the particles and/or field in question as test particles and/or fields in a given space-time, i.e. they are assumed not to affect the metric of space-time in any way. In typical space-times without closed time-like curves this means that one has, in essence, complete freedom of matter distribution on a space-like hypersurface. (See response 2 for some more discussion of this issue). The constraints imposed by the possibility of time travel have a quite different origin and are implausible. In the ordinary case there is a causal interaction between matter and space-time that results in relations between global structure of space-time and the matter distribution in it. In the time travel case there is no such causal story to be told: there simply has to be some pre-established harmony between the global space-time structure and the matter distribution on some space-like surfaces. This is implausible.

Response 2. Constraints upon matter distributions are nothing new. For instance, Maxwell's equations constrain electric fields **E** on an initial surface to be related to the (simultaneous) charge density distribution ρ by the equation ρ = div(**E**). (If

we assume that the E field is generated solely by the charge distribution, this conditions amounts to requiring that the E field at any point in space simply be the one generated by the charge distribution according to Coulomb's inverse square law of electrostatics.) This is not implausible divine harmony. Such constraints can hold as a matter of physical law. Moreover, if we had inferred from the apparent free variation of conditions on spatial regions that there could be no such constraints we would have mistakenly inferred that ρ = div(**E**) could not be a law of nature.

Counterresponse 2. The constraints imposed by the existence of closed time-like lines are of quite a different character from the constraint imposed by ρ = div(**E**). The constraints imposed by ρ = div(**E**) on the state on a space-like hypersurface are: (i) local constraints (i.e. to check whether the constraint holds in a region you just need to see whether it holds at each point in the region), (ii) quite independent of the global space-time structure, (iii) quite independent of how the space-like surface in question is embedded in a given space-time, and (iv) very simply and generally stateable. On the other hand, the consistency constraints imposed by the existence of closed time-like curves (i) are not local, (ii) are dependent on the global structure of space-time, (iii) depend on the location of the space-like surface in question in a given space-time, and (iv) appear not to be simply stateable other than as the demand that the state on that space-like surface embedded in such and such a way in a given space-time, do not lead to inconsistency. On some views of laws (e.g. David Lewis' view) this plausibly implies that such constraints, even if they hold, could not possibly be laws. But even if one does not accept such a view of laws, one could claim that the bizarre features of such constraints imply that it is implausible that such constraints hold in our world or in any world remotely like ours.

Response 3. It would be strange if there are constraints in the non-time travel region. It is not strange if there are constraints in the time travel region. They should be explained in terms of the strange, self-interactive, character of time travel regions. In this region there are time-like trajectories from points to themselves. Thus the state at such a point, in such a region, will, in a sense, interact with itself. It is a well-known fact that systems that interact with themselves will develop into an equilibrium state, if there is such an equilibrium state, or else will develop towards some singularity. Normally, of course, self-interaction isn't true instantaneous self-interaction, but consists of a feed-back mechanism that takes time. But in time travel regions something like true instantaneous self-interaction occurs. This explains why constraints on states occur in such time travel regions: the states ‘ab initio’ have to be ‘equilibrium states’. Indeed in a way this also provides some picture of why indeterminism occurs in time travel regions: at the onset of self-interaction states can fork into different equi-possible equilibrium states.

Counterresponse 3. This is explanation by woolly analogy. It all goes to show that time travel leads to such bizarre consequences that it is unlikely that it occurs in a world remotely like ours.

Response 4. All of the previous discussion completely misses the point. So far we have been taking the space-time structure as given, and asked the question whether a given time travel space-time structure imposes constraints on states on (parts of) space-like surfaces. However, space-time and matter interact. Suppose that one is in a space-time with closed time-like lines, such that certain counterfactual distributions of matter on some neighborhood of a point *p* are ruled out if one holds that space-time structure fixed. One might then ask "Why does the actual state near *p* in fact satisfy these constraints? By what divine luck or plan is this local state compatible with the global space-time structure? What if conditions near *p* had been slightly different?". And one might take it that the lack of normal answers to these questions indicates that it is very implausible that our world, or any remotely like it, is such a time travel universe. However the proper response to these question is the following. There are no constraints in any significant sense. If they hold they hold as a matter of accidental fact, not of law. There is no more explanation of them possible than there is of any contingent fact. Had conditions in a neighborhood of *p* been otherwise, the global structure of space-time would have been different. So what? The only question relevant to the issue of constraints is whether an arbitrary state on an arbitrary spatial surface *S* can always be embedded into a space-time such that that state on *S* consistently extends to a solution on the entire space-time.

But we know the answer to that question. A well-known theorem in general relativity says the following: any initial data set on a three dimensional manifold *S* with positive definite metric has a unique embedding into a maximal space-time in which *S* is a Cauchy surface (see e.g. Geroch and Horowitz 1979, p. 284 for more detail), i.e. there is a unique largest space-time

which has *S* as a Cauchy surface and contains a consistent evolution of the initial value data on *S*. Now since *S* is a Cauchy surface this space-time does not have closed time like curves. But it may have extensions (in which *S* is not a Cauchy surface) which include closed timelike curves, indeed it may be that any maximal extension of it would include closed timelike curves. (This appears to be the case for extensions of states on certain surfaces of Taub-NUT space-times. See Earman and Smeenk 1999). But these extensions, of course, will be consistent. So properly speaking, there are no constraints on states on space-like surfaces. Nonetheless the space-time in which these are embedded may or may not include closed time-like curves.

Counterresponse 4. This, in essence, is the stonewalling answer which we indicated at the beginning of section 2. However, whether or not you call the constraints imposed by a given space-time on distributions of matter on certain space-like surfaces ‘genuine constraints’, whether or not they can be considered lawlike, and whether or not they need to be explained, the existence of such constraints can still be used to argue that time travel worlds are so bizarre that it is implausible that our world or any world remotely like ours is a time travel world.

Suppose that one is in a time travel world. Suppose that given the global space-time structure of this world, there are constraints imposed upon, say, the state of motion of a ball on some space-like surface when it is treated as a test particle, i.e. when it is assumed that the ball does not affect the metric properties of the space-time it is in. (There is lots of other matter that, via the Einstein equation, corresponds exactly to the curvature that there is everywhere in this time travel worlds.) Now a real ball of course does have some effect on the metric of the space-time it is in. But let us consider a ball that is so small that its effect on the metric is negligible. Presumably it will still be the case that certain states of this ball on that space-like surface are not compatible with the global time travel structure of this universe.

This means that the actual distribution of matter on such a space-like surface can be extended into a space-time with closed time-like lines, but that certain counterfactual distributions of matter on this space-like surface can not be extended into the same space-time. *But note that the changes made in the matter distribution (when going from the actual to the counterfactual distribution) do not in any non-negligible way affect the metric properties of the space-time.* Thus the reason why the global time travel properties of the counterfactual space-time have to be significantly different from the actual space-time is not that there are problems with metric singularities or alterations in the metric that force significant global changes when we go to the counterfactual matter distribution. The reason that the counterfactual space-time has to be different is that in the counterfactual world the ball's initial state of motion starting on the space-like surface, could not ‘meet up’ in a consistent way with its earlier self (could not be consistently extended) if we were to let the global structure of the counterfactual space-time be the same as that of the actual space-time. Now, it is not bizarre or implausible that there is a counterfactual dependence of manifold structure, even of its topology, on matter distributions on spacelike surfaces. For instance, certain matter distributions may lead to singularities, others may not. We may indeed in some sense have causal power over the topology of the space-time we live in. But this power normally comes via the Einstein equations. But it is bizarre to think that there could be a counterfactual dependence of global space-time structure on the arrangement of certain tiny bits of matter on some space-like surface, where changes in that arrangement by assumption do not affect the metric *anywhere in space-time in any significant way*. It is implausible that we live in such a world, or that a world even remotely like ours is like that.

Let us illustrate this argument in a different way by assuming that wormhole time travel imposes constraints upon the states of people prior to such time travel, where the people have so little mass/energy that they have negligible effect, via the Einstein equation, on the local metric properties of space-time. Do you think it more plausible that we live in a world where wormhole time travel occurs but it only occurs when people's states are such that these local states happen to combine with time travel in such a way that nobody ever succeeds in killing their younger self, or do you think it more plausible that we are not in a wormhole time travel world?[4]

Quantum Mechanics to the Rescue?

There has been a particularly clear treatment of time travel in the context of quantum mechanics by David Deutsch (see

Deutsch 1991, and Deutsch and Lockwood 1994) in which it is claimed that quantum mechanical considerations show that time travel never imposes any constraints on the pre-time travel state of systems. The essence of this account is as follows.

A quantum system starts in state *S*1, interacts with its older self, after the interaction is in state S_2, time travels while developing into state S_3, then interacts with its younger self, and ends in state S_4 (see figure 10).

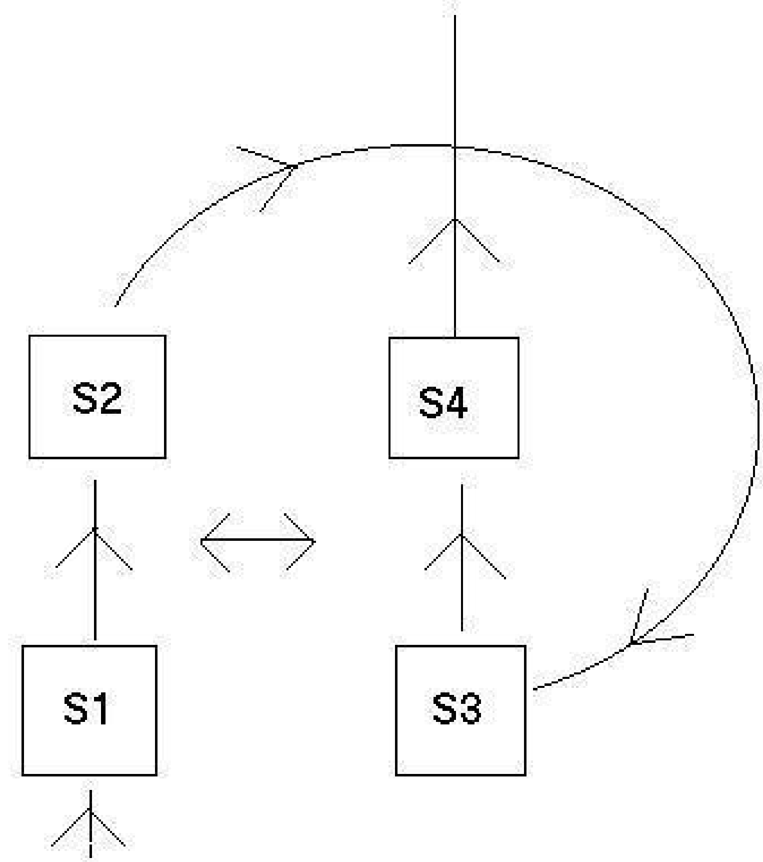

Figure 10

Deutsch assumes that the set of possible states of this system are the mixed states, i.e. are represented by the density matrices over the Hilbert space of that system. Deutsch then shows that for any initial state S_1, any unitary interaction between the older and younger self, and any unitary development during time travel, there is a consistent solution, i.e. there is at least one pair of states S_2 and S_3 such that when S_1 interacts with S_3 it will change to state S_2 and S_2 will then develop into S_3. The states S_2, S_3 and S_4 will typically be not be pure states, i.e. will be non-trivial mixed states, even if S_1 is pure. In order to understand how this leads to interpretational problems let us give an example. Consider a system that has a two dimensional Hilbert space with as a basis the states $|+\rangle$ and $|-\rangle$. Let us suppose that when state $|+\rangle$ of the young system encounters state $|+\rangle$ of the older system, they interact and the young system develops into state $|-\rangle$ and the old system remains in state $|+\rangle$. In obvious notation:

$|+\rangle_1|+\rangle_3$ develops into $|-\rangle_2|+\rangle_4$.

Similarly, suppose that:

$|+\rangle_1|-\rangle_3$ develops into $|+\rangle_2|-\rangle_4$,

$|-\rangle_1|+\rangle_3$ develops into $|-\rangle_2|-\rangle_4$, and

$|-\rangle_1|-\rangle_3$ develops into $|+\rangle_2|+\rangle_4$.

Let us furthermore assume that there is no development of the state of the system during time travel, i.e. that $|+\rangle_2$ develops into $|+\rangle_3$, and that $|-\rangle_2$ develops into $|-\rangle_3$.

Now, if the only possible states of the system were $|+\rangle$ and $|-\rangle$ (i.e. if there were no superpositions or mixtures of these states), then there is a constraint on initial states: initial state $|+\rangle_1$ is impossible. For if $|+\rangle_1$ interacts with $|+\rangle_3$ then it will develop into $|-\rangle_2$, which, during time travel, will develop into $|-\rangle_3$, which inconsistent with the assumed state $|+\rangle_3$. Similarly if $|+\rangle_1$ interacts with $|-\rangle_3$ it will develop into $|+\rangle_2$, which will then develop into $|+\rangle_3$ which is also inconsistent. Thus the system can not start in state $|+\rangle_1$.

But, says Deutsch, in quantum mechanics such a system can also be in any mixture of the states $|+\rangle$ and $|-\rangle$. Suppose that the older system, prior to the interaction, is in a state S_3 which is an equal mixture of 50% $|+\rangle_3$ and 50% $|-\rangle_3$. Then the younger system during the interaction will develop into a mixture of 50% $|+\rangle_2$ and 50% $|-\rangle_2$, which will then develop into a mixture of 50% $|+\rangle_3$ and 50% $|-\rangle_3$, which is consistent! More generally Deutsch uses a fixed point theorem to show that no matter what the unitary development during interaction is, and no matter what the unitary development during time travel is, for any state S_1 there is always a state S_3 (which typically is not a pure state) which causes S_1 to develop into a state S_2 which develops into that state S_3. Thus quantum mechanics comes to the rescue: it shows in all generality that no constraints on initial states are needed!

One might wonder why Deutsch appeals to mixed states: will superpositions of states $|+\rangle$ and $|-\rangle$ not suffice? Unfortunately such an idea does not work. Suppose again that the initial state is $|+\rangle_1$. One might suggest that that if state S_3 is $1/\sqrt{2}\,|+\rangle_3 + 1/\sqrt{2}\,|-\rangle_3$ one will obtain a consistent development. For one might think that when initial state $|+\rangle_1$ encounters the superposition $1/\sqrt{2}\,|+\rangle_3 + 1/\sqrt{2}\,|-\rangle_3$, it will develop into superposition $1/\sqrt{2}\,|+\rangle_2 + 1/\sqrt{2}\,|-\rangle_2$, and that this in turn will develop into $1/\sqrt{2}\,|+\rangle_3 + 1/\sqrt{2}\,|-\rangle_3$, as desired. However this is not correct. For initial state $|+\rangle_1$ when it encounters $1/\sqrt{2}\,|+\rangle_3 + 1/\sqrt{2}\,|-\rangle_3$, will develop into the entangled state $1/\sqrt{2}\,|-\rangle_2|+\rangle_4 + 1/\sqrt{2}\,|+\rangle_2|-\rangle_4$. In so far as one can speak of the state of the young system after this interaction, it is in the mixture of 50% $|+\rangle_2$ and 50% $|-\rangle_2$, not in the superposition $1/\sqrt{2}\,|+\rangle_2 + 1/\sqrt{2}\,|-\rangle_2$. So Deutsch does need his recourse to mixed states.

This clarification of why Deutsch needs his mixtures does however indicate a serious worry about the simplifications that are part of Deutsch's account. After the interaction the old and young system will (typically) be in an entangled state. Although for purposes of a measurement on one of the two systems one can say that this system is in a mixed state, one can not represent the full state of the two systems by specifying the mixed state of each separate part, as there are correlations between observables of the two systems that are not represented by these two mixed states, but are represented in the joint entangled state. But if there really is an entangled state of the old and young systems directly after the interaction, how is one to represent the subsequent development of this entangled state? Will the state of the younger system remain entangled with the state of the older system as the younger system time travels and the older system moves on into the future? On what

space-like surfaces are we to imagine this total entangled state to be? At this point it becomes clear that there is no obvious and simple way to extend elementary non-relativistic quantum mechanics to space-times with closed time-like curves. There have been more sophisticated approaches than Deutsch's to time travel, using technical machinery from quantum field theory and differentiable manifolds (see e.g. Friedman et al 1991, Earman and Smeenk 1999, and references therein). But out of such approaches no results anywhere near as clear and interesting as Deutsch's have been forthcoming.

How does Deutsch avoid these complications? Deutsch assumes a mixed state S_3 of the older system prior to the interaction with the younger system. He lets it interact with an arbitrary pure state S_1 younger system. After this interaction there is an entangled state S' of the two systems. Deutsch computes the mixed state S_2 of the younger system which is implied by this entangled state S'. His demand for consistency then is just that this mixed state S_2 develops into the mixed state S_3. Now it is not at all clear that this is a legitimate way to simplify the problem of time travel in quantum mechanics. But even if we grant him this simplification there is a problem: how are we to understand these mixtures?

If we take an ignorance interpretation of mixtures we run into trouble. For suppose that we assume that in each individual case each older system is either in state $|+\rangle_3$ or in state $|-\rangle_3$ prior to the interaction. Then we regain our paradox. Deutsch instead recommends the following, many worlds, picture of mixtures. Suppose we start with state $|+\rangle_1$ in all worlds. In some of the many worlds the older system will be in the $|+\rangle_3$ state, let us call them *A*-worlds, and in some worlds, *B*-worlds, it will be in the $|-\rangle_3$ state. Thus in *A*-worlds after interaction we will have state $|-\rangle_2$, and in *B*-worlds we will have state $|+\rangle_2$. During time travel the $|-\rangle_2$ state will remain the same, i.e turn into state $|-\rangle_3$, but the systems in question will travel from *A*-worlds to *B*-worlds. Similarly the $|+\rangle_2$ states will travel from the *B*-worlds to the *A*-worlds, thus preserving consistency.

Now whatever one thinks of the merits of many worlds interpretations, and of this understanding of it applied to mixtures, in the end one does not obtain genuine time travel in Deutsch's account. The systems in question travel from one time in one world to another time in another world, but no system travels to an earlier time in the same world. (This is so at least in the normal sense of the word ‘world’, the sense that one means when, for instance, one says "there was, and will be, only one Elvis Presley in this world".) Thus, even if it were a reasonable view, it is not quite as interesting as it may have initially seemed.

Conclusions

What remains of the killing-your-earlier-self paradox in general relativistic time travel worlds is the fact that in some cases the states on edgeless spacelike surfaces are ‘overconstrained’, so that one has less than the usual freedom in specifying conditions on such a surface, given the time-travel structure, and in some cases such states are ‘underconstrained’, so that states on edgeless space-like surfaces do not determine what happens elsewhere in the way that they usually do, given the time travel structure. There can also be mixtures of those two types of cases. The extent to which states are overconstrained and/or underconstrained in realistic models is as yet unclear, though it would be very surprising if neither obtained. The extant literature has primarily focused on the problem of overconstraint, since that, often, either is regarded as a metaphysical obstacle to the possibility time travel, or as an epistemological obstacle to the plausibility of time travel in our world. As we have discussed, using responses and counterresponses, it is not entirely clear that it is indeed an epistemological or a metaphysical obstacle. It is true that our world would be quite different from the way we normally think it is, if states were overconstrained given the time travel structure. If anything, underconstraint seems even more bizarre to us than overconstraint. However, time travel is quite strange to begin with, and it does not appear to be a terribly strong additional argument against time travel that it has strange consequences.

Notes to Time Travel and Modern Physics

Notes

[1.] Multiple collisions are handled in the obvious way by continuity considerations: just continue straight lines through the collision point and identify which particle is which by their ordering in space.

[2.] The dynamics here is radically non-time-reversible. Indeed, the dynamics is deterministic in the future direction but not in the past direction.

[3.] One might hope that fixed point theorems can be used to prove the existence of solutions in this type of cases too. Consider, for instance, a fixed initial state of motion I of the ball. Then consider all the possible velocities and locations and times $<v,x,t>$ at which such a ball could enter mouth 1 of the wormhole. Each such triple $<v,x,t>$ will determine the trajectory of that ball out of mouth 2. One can then look at the continuation of the trajectory from state I and that from state s, and see whether these trajectories collide. Then one can see for each possible triple $<v,x,t>$ whether the ball that starts in state I will be collided into mouth 1, and if it is, with which speed at what location and at which time this will occur. Thus given state I, each triple $<v,x,t>$ maps onto another triple $<v',x',t'>$. One might then suggest appealing to a fixed point theorem to argue that there must be a solution for each initial state I. However, in the first place the set of possible speeds and times are open sets. And in the second place there can be multiple wormhole traversals. Thus the relevant total state-space of wormhole mouth crossings consists of discretely many completely disconnected state-spaces (with increasing numbers of dimensions). So standard fixed point theorems do not apply directly. It should be noted that the results that have been achieved regarding this case do make use of fixed points theorems quite extensively. But their application is limited to certain sub-problems, and do not yield a fully general proof of the lack of constraints for arbitrary I.

[4.] This argument, especially the second illustration of it, is similar to the one in Horwich 1987, p 124-128. However, we do not share Horwich's view that it only tells against time travel of humans into their local past.

The Epistemology of Religion

Contemporary epistemology of religion may conveniently be treated as a debate over whether Evidentialism applies to the belief-component of religious faith, or whether we should instead adopt a more permissive epistemology. Here by Evidentialism I mean the initially plausible position that a belief is warranted only if "it is proportioned to the evidence". Evidentialism implies that it is not warranted to have a full religious belief unless there is conclusive evidence for it. It follows that if the known arguments for there being a God, including any arguments from religious experience, are at best probable ones, no one would be warranted in having full belief that there is a God. And the same holds for other religious beliefs, such as the Christian belief that Jesus was God incarnate. Likewise, it would be unwarranted to believe even with less than full confidence if there is not a balance of evidence for belief.

Simplifications

Epistemology is confusing because there are several sorts of items to be evaluated and several sorts of evaluation. Since the topic of this article is the epistemology of religion not general epistemology I shall simplify matters by assuming that what is being evaluated is something related to faith, namely individual religious beliefs, and that the way of evaluating religious beliefs is as warranted or unwarranted. (See Plantinga 1993a: 3-5 for the characterisation of warrant in terms of knowledge.)

I shall also ignore disputes between coherence theorists and foundationalists; disputes between internalists and externalists and disputes over whether belief is voluntary. Although these have some implications for the epistemology of religion they are primarily topics in general epistemology.

The Rejection of Enlightenment Evidentialism

Most contemporary epistemology of religion is *postmodern* in being a reaction to the Enlightenment thesis of the *hegemony* of Evidentialism. I discuss hegemony below, but let us first consider Evidentialism. This is the initially plausible position that a belief is warranted only if "it is proportioned to the evidence". (Beliefs proportioned to the evidence include, as a degenerate case, the evidence itself.) Here several sorts of evidence are allowed. One consists of beliefs in that which is "evident to the senses", that is, beliefs directly due to sense-experience. Another sort of evidence is that which is "self-evident", that is, obvious once you think about it. Evidence may also include the beliefs directly due to memory and introspection. Again moral convictions might count as evidence, even if not treated as "self-evident". But in order to state the sort of Evidentialism characteristic of Enlightenment thought, I stipulate that no beliefs asserting the content of religious or mystical experiences count as evidence. That does not prevent the fact that someone has had a religious experience with a certain content as counting as evidence. Likewise the fact that various people report miracles counts as evidence.

Evidentialism implies that it is not warranted to have a full religious belief (ie a religious belief held with full confidence) unless there is conclusive evidence for it. The content of religious experience has been stipulated not to count as evidence. Religious beliefs do not seem to be self-evident. So the only available evidence would seem to be non-religious premisses, from which the religious beliefs are inferred. Therefore, the only way of deciding whether the religious beliefs are warranted would be to examine various arguments with the non-religious beliefs as premisses and the religious beliefs as conclusions.

According to Evidentialism it follows that if the known arguments for there being a God, including any arguments from religious experience, are at best probable ones, no one would be warranted in having full belief that there is a God. And the same holds for other religious beliefs, such as the Christian belief that Jesus was God incarnate. Likewise, it would be unwarranted to believe even partially (ie with less than full confidence) if there is not a balance of evidence for belief.

In fact it seems that many religious believers combine full belief with "doubts" in the sense of some reasons for doubting, or they combine partial belief with what they take to be weighty reasons for disbelief. According to Evidentialism they are unwarranted. Other believers consider that, on reflection, they have little reason for doubting but that they have almost no positive evidence for their religious beliefs. According to Evidentialism they too are unwarranted. This raises the question, how can we adjudicate between an epistemological thesis which might otherwise be believed and a religious belief which that thesis implies is unwarranted? One component of the Enlightenment (with the notable exception of Hume) was the *hegemony* of epistemology. By that I mean the assumptions that (a) we can discover the correct epistemology in isolation from discovering actual human tendencies to form beliefs, and that (b) we have an overriding reason to use this epistemology to correct those tendencies. If,

according to Evidentialism, full or even partial religious beliefs were unwarranted, then, given the hegemony of epistemology we have an overriding reason to reject those beliefs. Perhaps the clearest exponent of this position is the comparatively recent Clifford whose use of moral vocabulary conveys well the overriding character of the reasons epistemology is meant to provide. His position is summed up in the famous quote: "It is wrong always, everywhere, and for anyone, to believe anything upon insufficient evidence" (Clifford 1879: 186).

At the other extreme from Clifford is the position of Fideism, namely that if an epistemological theory such as Evidentialism conflicts with the warrant of religious beliefs then that is so much the worse for the epistemological theory.

The Enlightenment position was the hegemony of *Evidentialism*. Its rejection is quite compatible with holding a hegemony thesis for a fragment of epistemology, weaker than Evidentialism. Such a fragment might, for instance, contain the principle of self-referential consistency, relied upon by Plantinga (1983: 60). This states that it is not warranted to have a belief according to which that belief is itself not warranted.

As I understand it, postmodernism implies more than being postmodern in my sense. Postmodernism is the rejection of the hegemony of even a fragment of epistemology. That might seem agreeable to fideists. Postmodernism tends, however, to trivialise Fideism by obliterating any contrast between faith in divine revelation and trust in human capacities to discover the truth.

Much contemporary epistemology of religion seeks to avoid the extremes both of the Enlightenment Evidentialism and of Fideism. It is thus postmodern without necessarily being postmodernist. Let us call the injunction to avoid these extremes the *problematic* of contemporary epistemology of religion.

Evidentialism Defended

One response to the problematic is to separate Evidentialism from the hegemony of epistemology. Evidentialism may then be argued for by noting how we implicitly rely upon evidentialist principles in many different areas of enquiry, or by noting which principles generalise various particular examples of warranted and unwarranted reasoning. Such a defence of Evidentialism is part of the project of some contemporary philosophers who seek to attack theism in favour of agnosticism and/or atheism. This defence may well be implicit in Flew’s famous "The Presumption of Atheism" (1972). It is more explicit in Scriven’s *Primary Philosophy* (1966, ch 4). Scriven anbd Flew are relying on the Ockhamist principle that, in the absence of evidence for the existence of things of kind X, belief in Xs is unwarranted. This they can defend by means of examples in which non-Ockhamist thinking is judged unwarranted. So even if the whole of Evidentialism is not defended the Ockhamist fragment of it may be.

Not surprisingly the reliance of non-theist philosophers on Evidentialism has been criticised. First there is an ad hominem. Shalkowski (1989) has pointed out that these defenders of Evidentialism tend in fact

to be atheists not agnostics, yet a careful examination, he says, of the examples used to support Ockham's Razor show that either they are ones in which there is independent evidence for denying the existence of Xs or ones in which suspense of judgement seems to be the appropriate response, not denial. Another criticism is Plantinga's claim that Evidentialism is self-referentially inconsistent for there is no evidence for Evidentialism (Plantinga 1983: 60). This might be met in either of two ways. First, it could be said that all that is being defended is the Ockhamist fragment of Evidentialism and that this is not itself vulnerable to Ockham's Razor. Or it could be argued that deriving an epistemology from a wide range of examples is evidence for it. To be sure this is far from conclusive evidence. But even a less than full belief in an epistemological thesis which showed theism to be unwarranted would be damaging. This may be illustrated using an example with artificial numerical precision: 80% confidence in an epistemology which showed that no degree of belief in theism greater than 60% was warranted would demonstrate, I take it, that no degree belief in theism greater than 68% was warranted.(68% = 20% plus 80% of 60%.)

Natural theology

Theistic philosophers may, of course, grant Evidentialism and even grant its hegemony, but defend theism by providing the case which evidentialists demand. Here the details of the arguments are not within the scope of an article on epistemology. What is of interest is the kind of argument put forward. For a start there is the project of *demonstrating* God's existence, and this project is not restricted to neo-Thomists. (See Craig 1979, Braine 1988, Miller 1991.)To show the warrant of full belief that there is a God it is sufficient (a) to have a deductively valid argument from premisses which are themselves warrantably held with full belief unless defeated by an objection and (b) to have considered and defeated all available objections to either the premisses, the conclusion or any intermediate steps. Some of the premisses of these argument are said to be self-evident, that is obvious once you think about it. (Eg the denial of the explanatory power of an infinite causal regress, or the principle that the existence of any composite thing needs to be explained). And that raises a further epistemological problem. Does something's being self-evident to me warrant my full belief in it even if I know of those of equal or greater intellectual ability to myself to whom it is not self-evident?

Many natural theologians have, however, abandoned the search for demonstrative arguments, appealing instead to ones which are probable, either in sense of having weight but being inconclusive or in the sense of having a mathematical probability assigned to them. Notable in this regard are Mitchell's cumulative argument (Mitchell 1973) and Swinburne's Bayesian reliance on probability (Swinburne 1979). In a popular exposition of his argument Swinburne appeals instead to an inference to the best explanation (Swinburne 1995; see also Forrest 1996). While there are differences of approach, the common theme is that there is evidence for theism but evidence of a probable rather than a conclusive kind, warranting belief but not full belief.

The Relevance of Newman

Although pre-dating the current debate, Newman's rejection of Locke's and Paley's Evidentialism is relevant to the problematic of contemporary epistemology of religion. First he quite clearly rejected the hegemony of epistemology. His procedure was to examine how in fact people made up their minds on non-religious issues and argue that by the same standards religious beliefs were warranted. As a result he qualified Evidentialism by insisting that an *implicit* and *cumulative* argument could lead to warranted certainty. (See Mitchell 1990.)

Newman's position has two interpretations. One, which differs little from Swinburne's probabilistic approach to natural theology, asserts that the consilience of a number of independent pieces of probable reasoning can result in a probability so high as to be negligibly different from certainty. If, to use an example Newman would not have liked, Aquinas's five ways were independent and each had probability 75% then taken together their probability is about 99.9%. One difficulty with this interpretation is that even a highly probable argument differs from a demonstration in that the former is vulnerable to probabilistic counter-arguments. Thus a probabilistic version of the Argument from Evil might subsequently reduce the probability from 99.9% down to 75% again.

The other interpretation of Newman's position is to say that Evidentialism falsely presupposes that there are fine gradations on a scale from full belief through partial belief to partial disbelief to full disbelief. Newman claims we are not like that when it comes to those beliefs which form part of religious faith. In such cases the only available states are those of full belief and full disbelief or, perhaps, full belief, and lack of full belief. Of course we can believe that theism has a probability between 90% and 60%, say, but that could be interpreted as believing that relative to the evidence theism has a probability between 90% and 60%, which, in turn, is a comment on the strength of the case for theism not the expression of a merely partial belief.

If Newman is right then Evidentialism is slightly wrong. Instead of requiring belief to be proportioned to the evidence, full belief is warranted if the case for it holds "on the balance of probabilities". In that case a natural theology, such as Swinburne's, consisting of merely probable arguments can still show full religious belief to be warranted.

Wittgensteinian Fideism

Another reaction to the problematic is Wittgensteinian Fideism. I take this to be thesis that there are various different "language games", and that while we can ask questions about warrant within a language game it is a mistake to ask about the warrant of "playing" the game in question. In this way epistemology is relativised to language games, themselves related to forms of life, and the one used for assessing religious claims is less stringent than Evidentialism. Here there seems to be both an autonomy thesis and an incommensurability thesis. The autonomy thesis tells us that religious utterances are only to be judged as warranted or unwarranted by the standards implicit in the religious form of life, and this may be further restricted to Christianity or Hinduism, or any other religion (Malcolm 1992). The incommensurability thesis tells us that religious utterances are unlike scientific or metaphysical claims and so we are confusing different uses of language if we judge religious utterances by the standards of

science or metaphysics (Phillips 1992). Stress on the autonomy thesis brings Wittgensteinian Fideism close to the Fideism of many religious conservatives, but stress on the incommensurability thesis brings it close to the extreme liberal position of Braithwaite (1955), namely that religion is about attitudes not facts, which would, of course, be rejected by religious conservatives.

Perhaps the most obvious criticism of Wittgensteinian Fideism is that even if the underlying theory of forms of life and language games is granted it is an historical fact, warranted by the criteria of the "game" of history, that the tradition to which the majority of Jews, Christians and Muslims belong to is a form of life with heavy metaphysical commitments, and in which such utterances as "There is a God" are intended as much like "There is a star ten times more massive than the Sun" as like "There is hope". So Wittgensteinian Fideism is only appropriate for such religions as Zen Buddhism and for some, relatively recent, liberal strands of Judaism and Christianity which have rejected the traditional metaphysical commitment (as in Cupitt 1984).

We could modify the Wittgensteinian position to allow a metaphysical "language game" with its own criteria for warrant etc, and in which natural theology should be pursued. Then the Judo-Christian-Islamic "language game" would be part of this larger, autonomous metaphysical "language game". That modified account would cohere with the historical fact of the metaphysical commitment of that religious tradition. In that case, though, it would seem that, not just the Judo-Christian-Islamic "language game", but all serious intellectual enquiry should also be treated as parts of the one "game", with one set of rules. Thus Wittgensteinian Fideism would have been qualified out of existence.

Even if we reject Wittgensteinian Fideism we might still take a lesson from it. For it must surely be granted that religious utterances are not made in a purely intellectual way. Their entanglement with commitment to a way of life and their emotional charge might help to explain the fact, if it is one, that those who take religion seriously, whether believers or not, do not in fact have a continuous range of degrees of confidence but operate instead with full belief or full disbelief. For, normally, emotionally charged beliefs are either full on or full off, and in abnormal cases tend to be divided rather than partial. Thus, confronted with conflicting evidence about whether your affection is reciprocated you are far less likely to suspend judgement than to oscillate between full belief and full disbelief. Likewise it seems more normal to oscillate between full belief in God in moments of crisis and full disbelief when things go well than to suspend judgement at all times. This ties in with the Newmanian modification of Evidentialism, mentioned above.

Reformed Epistemology

An influential contemporary rejection of Evidentialism is Reformed Epistemology, due to Wolterstorff (1976) and Plantinga (1983). As Plantinga develops it, beliefs are warranted without Enlightenment-approved evidence provided they are (a) grounded, and (b) defended against known objections. Such beliefs then can themselves be used as evidence for other beliefs. Quite what grounding amounts to could be debated. Recently, however, Plantinga has proposed an account of warrant as proper functioning. This account seems to entail that S’s belief that p is grounded in event E if (a) in the circumstances E caused S

to believe that p, and (b) S’s coming to believe that p was a case of proper functioning (Plantinga 1993b).

While the details of grounding might be controversial I shall assume that reformed epistemologists assert that ordinary religious experiences of awe, gratitude, contrition, etc ground the beliefs implied by believer’s sincere reports of such experiences, provided they can be said to cause those beliefs. Such grounded beliefs are warranted provided they can be defended against known objections. They can then be used as evidence for further religious beliefs. Thus if religious experience grounds the belief that God has forgiven me for doing what is wrong to other humans beings, then that is evidence for a personal God who acts in a morally upright fashion. For, it can be argued, only such a God would find anything to forgive in the wrongs I do to my fellow human beings.

One difference between Reformed Epistemology and Fideism is that the former requires defence against known objections, such as the Argument from Evil, which the latter might dismiss such objections as either irrelevant or, worse, intellectual temptations.

Reformed Epistemology could be correct and yet far less significant than its proponents take it to be. That would occur if in fact rather few religious beliefs are grounded in the sorts of ordinary religious experiences most believers have. For it may well be that the beliefs are part of the cause of the experience rather than the other way round (Katz 1978).

One way of comparing Reformed Epistemology with Wittgensteinian Fideism is to note that the former proposes a universal relaxation of the stringent conditions of Evidentialism while the latter only proposes a relaxation for the case of religious beliefs.

Religious Experience, Revelation and Tradition

Reformed Epistemology may be thought of as a modification of Evidentialism in which the permissible kinds of evidence are expanded. In this context we should note especially Alston’s work arguing that certain kinds of religious experience can be assimilated to perception (Alston 1991).

The difference between Reformed Epistemology and Evidentialism is also shown by a consideration of revelation and inspiration. An evidentialist will consider arguments from the premiss that it is said such and such was revealed or the premiss that so and so claimed to be inspired by God, but a reformed epistemologist might allow as warranted religious beliefs grounded in the event of revelation or inspiration. Thus Mavrodes has argued that any belief due to a genuine revelation is warranted, and has discussed several modes of revelation (Mavrodes 1988). This would have the, to my mind unacceptable, consequence that warrant becomes totally inaccessible either to the person concerned or the community (Zagzebski 1993a:204-205). A similar criticism could be made of beliefs grounded in religious experience. In both cases, the question of whether a belief is genuinely grounded in religious experience or is genuinely grounded in inspiration is one that several religious traditions have paid attention to, with such theories as that of discernment of spirits (Murphy, 1990, ch 5).

Finally in what might be called Counter-Reformed Epistemology it could be allowed that a belief can be warranted if grounded in a religious tradition. Such a belief would have to be caused in the right sort of way by the right sort of tradition. As in the previous cases we might note that such grounding should be partially accessible to the believer. As far as I know rather little work has been done on this extension of Reformed Epistemology, but the social dimension of warrant has been noted (Zagzebski 1993a).

Informal Logic

Sometimes informal logic is portrayed as a theoretical alternative to formal logic. While some informal logicians may see the discipline this way, this description places too much emphasis on a rejection of formal methods of analysis -- a rejection which does not characterize all informal logicians. The field can, therefore, be better described as the attempt to develop logical tools that can analyze and assess the "informal" reasoning that occurs in natural language contexts in, for example, political debate, legal proceedings, social commentary, and the opinion pieces featured in the mass media (in newspapers, magazines, television, the Internet, and so on).

Historically, informal logic can be described as a field which has ‘broken away’ from formal logic. In some cases, this break is characterized by a vehement rejection of formal methods of analysis but the relationship of the latter to informal logic is a matter of dispute. Few commentators would maintain that formal methods can be applied with full rigor, but many believe that they can contribute to an understanding of informal reasoning and much of the work in the field assumes a premise/conclusion model of argument which is derived from a formal paradigm. In the future, informal logic may be linked to formal logic by attempts to convert its insights into formal analogues which can be used to construct computer models of natural language reasoning, in research in AI (Artificial Intelligence), and so on.

Three distinct approaches to argument characterize informal logic. The first is founded on fallacy theory, the second is rhetorical, and the third is dialogical. The fallacy approach has been criticized by many theorists and is slowly giving way to a more general account of good reasoning which subsumes it. The account of argument that results establishes the criteria for good causal arguments, arguments by analogy, etc., and treats fallacies as failures to live up to these criteria.

Many informal logicians borrow freely from all three of these approaches, and from a variety of related disciplines and traditions. Literature in the field may, in view of this, apply techniques borrowed from formal logic, philosophy of language, communication theory, game theory, AI, speech act theory and so on. Important topics in recent literature include legal argumentation, the viability of the distinction between linked and convergent premises, deductivism, enthymemes, relevance, the management of argumentative exchange, adversarial and non-adversarial models of argument, visual modes of reasoning, premise acceptability, the logic of humor, arguments by analogy, and antecedents of informal logic in ancient, medieval and early modern times.

History

The origins of informal logic are found in the call for more relevant higher education that characterizes the social and political movements of the nineteen sixties. In logic this precipitated a more concerted attempt to apply its methods to concrete examples of everyday reasoning. The beginning of informal logic is the attempt to replace the artificial examples that characterize earlier logic books (early editions of Copi, e.g.) with instances of reasoning, argument and debate which are directly taken from newspapers, television and the mass media.

In attempting to analyze such reasoning, informal logicians were greatly influenced by a number of earlier works which analyzes ordinary language arguments. Aristotle's treatment of fallacies and his theory of rhetoric remain a frequent basis for discussion and research. The two modern works which most anticipate and influence informal logic are Hamblin's *Fallacies* and Toulmin's *The Uses of Argument*. The latter is especially notable for its emphasis on "the standards and values of practical reasoning," as opposed to "the abstract and formal criteria relied on in mathematical logic and much twentieth century epistemology."

Informal logic proper begins in North America in the nineteen seventies. The most influential figures in its development are Ralph H. Johnson and J. Anthony Blair. Their *Logical Self-Defense* was one of the first introductory texts to emphasize concrete examples of informal reasoning and their *Informal Logic Newsletter* quickly became a focus for discussion, news and research. Now the journal *Informal Logic*, it remains a barometer for developments in the field in its eighteenth year of publication.

Other journals which have played a significant role in the development of informal logic include *Argumentation*, *Philosophy and Rhetoric*, *Argumentation and Advocacy* (formerly the *Journal of the American Forensic Association*) and *Teaching Philosophy*. Philosophy journals like the *American Philosophical Quarterly* and the *Canadian Journal of Philosophy* have also published significant articles in the field.

In keeping with an emphasis on concrete examples of actual reasoning, the development of informal logic has been tied to pedagogical discussions of the ways in which students can best be taught to reason well in the social, political and work related contexts. One prominent feature of the evolution of informal logic is, therefore, the publication of dozens (and probably hundreds) of textbooks designed to teach

students how to reason in such contexts. In many cases, these texts (e.g., those by Govier, Kahane and Ruggiero) are also of theoretical interest, for they implicitly or explicitly advocate and elaborate a particular theoretical approach.

Three Approaches

Early approaches to informal logic emphasized fallacy theory. Its limits have been the subject of a great deal of discussion and debate (witness the articles in Hans Hansen & Robert Pinto's *Fallacies*), but formal and informal fallacies continue to be a vigorous subject of research. Hamblin's treatment serves as a common reference point, as does the work of John Woods and Douglas Walton, who have discussed a great variety of fallacies in a series of articles and books, first as co-authors and then as individuals. It is notable that their early work (and Woods' later work) frequently employs formal methods of analysis.

One significant development in the literature on fallacies is a number of articles which point out that instances of traditional fallacies -- *ad bacculum*, *ad hominem*, two wrongs reasoning, etc. -- often constitute good arguments. Though many introductory textbooks have ignored such developments, those commentators who theoretically defend the fallacy approach have responded by developing a more careful treatment of the fallacies than was previously the case. Groarke, Tindale and Fisher have tried to consolidate concerns about individual fallacies by developing criteria that distinguish between good and bad variants of traditional fallacy forms, in the process exchanging fallacies for corresponding forms of good argument.

A second approach to informal logic borrows from rhetorical perspectives which include classical rhetoric (especially as it is found in Aristotle) and contemporary rhetorical theory. To a much greater extent that formal logic, they have traditionally addressed practical concerns about argument and persuasion. In the attempt to understand informal argument, much can be learned from their willingness to discuss and analyze features of informal reasoning that extend beyond traditional logical concerns. Rhetoric's emphasis on audience does, for example, underscore an essential ingredient of effective argument that extends beyond logical notions of validity and soundness: in a real life context, an argument which is sound (i.e. deductively valid with true premises) is unlikely to achieve its desired end if it is constructed in a way that violates the deeply held sentiments (the *pathos*) of its intended audience.

A third prominent approach to informal logic borrows from communication theory. It sees argumentation as a form of dialogical exchange and dispute resolution which must conform to implicit normative rules. These rules determine what moves and counter-moves are and are not acceptable in a dialogue. An understanding of such rules -- and a recognition that the rules for dialogue differ in different kinds of contexts (scientific, political, etc.) -- is, on this account, the key to understanding argument. Problems with particular arguments -- fallacies, for example -- are explained as violations of the rules of dialogue.

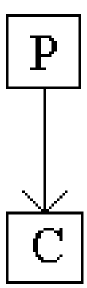
The foremost representative of the dialogical approach to informal logic is Douglas Walton. Like other commentators who develop this approach, he is greatly influenced by the Dutch "pragma-dialectic" theory of argumentation developed by Frans H. Van Eemeren and Rob Grootendorst of the University of

Amsterdam. Taken in conjunction with informal logic, the critical thinking movement and related disciplines, the latter has helped make argumentation theory an area of intensive international research and discussion (for a collection of papers which well represents the state of the art in this multi-disciplinary field, see van Eemeren et. al.).

An Example

The three approaches to informal logic can easily be demonstrated with a simple example which is taken from a Danish television debate over the question whether the Danish church should be separated from the Danish state (see Charlotte Jorgensen, "Hostility in public debate," in Van Eemeren et. al., Vol. IV). At one point in this debate, the debater arguing against the separation of church and state declares that "My opponent wants to sever the Danish church from the state for his own personal sake. His motion is an attempt to take over the church and further his ecumenical theology by his usual mafia methods."

We can plausibly understand this remark as a simple argument with one premise and an implicit (or "missing" or "hidden") conclusion. The premise (P) is the claim that "My opponent wishes to sever the Danish church from the state for the sake of his personal interests (i.e., in order to take it over and further his ecumenical theology by his usual mafia methods)." The implied conclusion (C) is the implicit claim that "We should (therefore) reject his motion to separate the Danish church and state." The argument can be diagrammed as:



Looked at from the point of view of fallacy theory, this is a classic case of *ad hominem*. Kahane, for example, describes it as a fallacy that occurs when an arguer is guilty "of attacking his opponent rather than his opponent’s evidence and arguments" (65). In this case, the debater in question attacks the motivation and the character of the person promoting a separate Danish church instead of showing what is wrong with his evidence for the claim that this is a good idea. On these grounds, the fallacy approach rejects the proposed reasoning as fallacious.

Though dialogical approaches employ a different theoretical structure, they invite a very similar analysis. Van Eemeren and Grootendorst explain ad hominem as a violation of their first rule for "critical discussion," which maintains that "Parties [to a dispute] must not prevent each other from advancing standpoints or casting doubts on arguments." Different kinds of *ad hominem* (i.e., abusive, circumstantial and *tu quoque ad hominem*) are construed as different violations of this rule. In the case in question, it suffices to say that the debater’s attack on his opponent illegitimately denies him his right to make a case

for his position.

Rhetorical approaches are characterized by a more sympathetic attitude to *ad hominem* arguments. This attitude can be understood in terms of Aristotle's suggestion that the *ethos* of a speaker plays a crucial role in determining whether an argument is persuasive or not. Looked at from this point of view, an *ad hominem* is, in principle, an acceptable attack on the *ethos* of a speaker (or writer). This being said, this particular example of *ad hominem* remains problematic, for it is founded on a very heavy handed and (at least in the excerpt we have looked at) unsubstantiated charge against the debater who advocates the separation of the Danish church and state. One might therefore argue that this kind of strongly worded charge undermines the ethos of the *speaker who forwards it* rather than the person he attacks.

It is significant that the rhetorical approach clearly recognizes that *ad hominem* attacks can be entirely appropriate. One may, to take a different example, reasonably cast doubt on an arguer's reasoning by pointing out that they lack the requisite knowledge to make appropriate judgments in the area in question, by pointing out that they have a vested interest, and so on. If someone with no physics credentials wishes to sell one a device to see quarks, then one might very reasonably dismiss their arguments with an *ad hominem*. Such appeals play an essential role in ordinary language reasoning, for time constraints make it impossible to carefully analyze all the arguments presented to us and we must therefore decide which ones we pay attention to by relying on an assessment of the arguer.

It is in this regard important to recognize that one can easily adapt dialogical and fallacy approaches to informal reasoning so that they too recognize the possibility of reasonable *ad hominem*s. If one adopts a fallacy approach, then this can be accomplished by defining *ad hominem* more narrowly, so that the fallacy only encompasses those attacks against the person which are fallacious. Alternatively, one can recognize *ad hominem* as in principle legitimate, but unreliable when it is not properly formulated -- when care is not taken to ensure that the argument in question does not attack an opponent's character in an irrelevant or an unsubstantiated manner).

If one adopts a dialogical approach, then one may recognize the possibility of good *ad hominem* reasoning by arguing that there are forms of dialogue which do not allow the participation of individuals who have vested interests or are in some other way not qualified to speak to an issue in some contexts. Such refinements are in keeping with our common understanding that, for example, a judge who adjudicates over a civil dispute must not have a vested interest in the outcome.

Relationship to Philosophy

Philosophy and philosophers have played a central role in defining informal logic and developing its approach to ordinary reasoning (communication theory and rhetoric have also made significant contributions). In part because of this, work in the field reflects philosophical concerns about the nature of rationality, the standards of good reasoning, the value of formal methods of analysis, the value of logic and rhetoric, and the social and political role of reasoning (especially in democracy). In the future, the analysis of ordinary reasoning which informal logic makes possible may allow new insights in

philosophy of mind, ethics and epistemology.

Within the subdisciplines of philosophy, the emphasis that informal logic places on natural language reasoning and on concrete examples of everyday argumentation might be readily compared to the emphasis that the various kinds of "applied ethics" (biomedical ethics, business ethics, etc.) place on concrete moral problems. In both cases, one finds an approach to philosophy which places great emphasis on its relevance to practical concerns. In many ways, one might compare this attitude to philosophy to the one that characterizes ancient philosophical perspectives which emphasize the ways in which philosophy can contribute to day to day life (e.g., Stoicism, Skepticism and Epicureanism).

The ideal theory of informal logic will encompass both a general theory of argument and a procedure for applying it to concrete instances of reasoning. If the field can avoid the fragmentation that has tended to accompany a sometimes staggering proliferation of approaches derived from a variety of related disciplines, the end result may be a model of ordinary argumentation which makes much better sense from an informal and a formal point of view.

Cosmology and Theology

Reasoning known as the cosmological argument (Burrill 1967; Craig 1979, 1980; Hepburn 1967) tries to justify belief in God by pointing to the existence of the cosmos, its causal orderliness, and alleged evidence of its being in some sense designed to include life and intelligence. [Often the appeal to such evidence is instead called the argument from design, or the teleological argument.] Some cosmologists believe, however, that the existence and order of the cosmos can be accounted for scientifically. Its life-permitting character might itself, they consider, be explained through its being divided into multiple domains worth the name of "universes". These could vary randomly in their features, ours being one of the perhaps very rare ones in which life had any chance of evolving. As the anthropic principle reminds us, only the life-permitting universes could give rise to observers. They should hesitate before concluding that an omnipotent, omniscient, all-creating person had made their surroundings life-permitting.

Philosophers, too, have doubted that so remarkable a person would be needed to explain such affairs, or that this person's own existence could be any less in need of explanation. They may here conceive God in a way not everybody would accept, interactions between cosmology and theology often depending on which picture of God is preferred. Such interactions include discussions of the nature of time and of the human mind, and of whether intelligent life is widespread in the cosmos.

Why is there a Cosmos?

People disagree over whether the sheer existence of the cosmos could call for explanation. Some have held that it always would, no matter how long the cosmos had existed; others that it never would; and still others that this would depend on whether the cosmos had existed eternally, or else on the nature of time.

It is nowadays usually believed that our universe came out of a Big Bang, a violent explosion occurring perhaps fifteen billion years ago. Thinking that the Bang could be explained only by God, the atheistic Hoyle (1950) preferred a universe existing eternally in a Steady State: it expanded, but new hydrogen atoms constantly materialized to keep the average cosmic density the same. Although at first offering no explanation for the new atoms, he thought them much less of a difficulty than the materialization of everything at once. Among theists, Pius XII (1952) then agreed that a Bang could indeed be counted as specially strong evidence of God's creative activity, yet many theologians protested that this activity should not be particularly associated with any first moment of a universe's existence. Tables, for instance, would vanish immediately if God failed to "conserve" their existence through exercise of his creative power.

When Hawking (1987, 1988) suggested that his own cosmology left "no place for a creator" since it made "What happened before the Bang, to cause it?" comparable to "What's Earth like to the north of the North Pole?", the theologians renewed their protests. They accompanied them with quotations from Saint Augustine, who had written that God created time and the world together. It is a theological commonplace, though, that God could be described as "creator" even of an eternally existing world. Both in theology and in philosophy, talk of creation or causation does not necessarily assume the temporal priority of creative or causal agencies. Descartes emphasized that in calling God "the cause of himself" he meant only that God's eternal existence was guaranteed by God's nature.

G.Gamow and W.B.Bonnor (both reprinted in Leslie ed. 1990) had meanwhile joined Hoyle in his eagerness to avoid a cosmic beginning. Gamow's article of 1954 favoured a universe which had contracted for infinitely long before rebounding in a Big Bang, whereas Bonnor's of 1960 proposed infinitely many oscillations, the rebounds always occurring before the cosmic material reached infinite densities, which Bonnor called "signs of error". In contrast, Milne (1952) welcomed the Bang as evidence of God's hand. He maintained, too, that the universe at the time of its creation had to be point-like and therefore infinitely dense. Creation of a spatially extended universe was a logical impossibility.

This last contribution to the debate was an outright blunder, there being no contradiction in the idea of creating something extended. Other contributions are harder to evaluate, for intuitions about what should be viewed as a universe's "natural state" -- where this means something not calling for explanation by a divine person or any other external factor -- can be defended or attacked only very controversially. Grünbaum (1990, and in Leslie ed. 1990) thinks it perverse to imagine that tables or the entire universe would disappear if God did nothing to prevent this; in his firm opinion, to discover what happens naturally we must look to see what actually occurs; while Hume (1739) holds that no cause would be needed even for the abrupt entry of a universe into a time which had previously been flowing. Yet one main message which many find in Hume's writings is that we can never learn anything from experience unless helped by various unprovable basic principles: for instance, that the future is likely to resemble the

past. Now, one such basic principle might be the need to deny that anything -- let alone an entire universe -- could come to exist for no reason whatever. True enough, quantum theory is often thought to tell us that the universe is indeterministic in some absolute way, but not even this would be a clear declaration that its existence could be utterly reasonless. Again, people can accept quantum laws without thinking that their operation is "natural" in the technical sense of not being a product of God's will.

If we saw a problem in a universe's existence, could it be removed by taking that universe to have existed for infinite past time? Some argue that this would allow its presence at any one instant to be explained by its presence at earlier instants; yet would they then say the same about, e.g., the notion that a particular book had existed eternally? Presumably not. Those Moslems who think the Koran eternal typically consider its existence due to an eternal divine decree. "It exists because it always has done" is not what they think. Moreover, there might be some force in the Kalam Cosmological Argument (Craig 1979) which opposes the world's eternity on the grounds that no infinite series of years could have been traversed to reach the present day. [A complicating factor is that whether the Big Bang's earliest, hottest stages were of finite or infinite duration might depend on one's choice of clock. What if infinitely many events occurred during those stages? The clocks most appropriate to timing the events might then show the stages as taking infinitely long to unfold. As measured by ours, such clocks would tick ever more slowly as the universe cooled.]

A better approach could be that of the quantum cosmologists, Vilenkin (1982) and Hawking (1987) for example, who speculate that quantum theory can give probabilities for worlds of certain kinds to exist. Many recent cosmological models have been inspired by E.P.Tryon's idea of 1973 (Leslie ed. 1990) that even very large universes could begin their existence by taking advantage of quantum indeterminism. Each universe would "cost" little or nothing since the energy tied up in all its particles could be cancelled by their gravitational potential energy, which is standardly treated as *negative energy*. They could therefore be akin to the quantum fluctuations in which individual particles such as electrons exist fleetingly by "borrowing" energies too small to upset quantum theory's rather disorderly balance sheets. It is at present unclear whether this could make sense except against the background of an already existing space, or at least a "space-time foam" lacking clear distinctions between space and time (see Atkins 1992; Craig and Smith 1993; Halliwell 1992; Russell, Murphy and Isham eds. 1996). A common verdict, though, is that even if no such background were needed, there could still be a problem of why quantum laws applied.

Causal Orderliness

Some read Kant as arguing that various principles which we apply to the world, for instance when we view it as causally ordered throughout, are valid only as giving insight into how we necessarily see things. Could this mean that the world was not itself ordered causally, the situation instead being that our unconscious minds were super-geniuses regulating everything we fancied we saw, to ensure that it all obeyed the laws of nature (quantum electrodynamics, general relativity, or whatever)? This would be bizarre, which leads many of Kant's admirers to suspect that he intended something more subtle. Admittedly the laws which people tend to regard as inviolable may some day break down; that is a

possibility which cosmologists find easy to defend, familiar as they are with the idea of cosmic "phase transitions" comparable to the change from ice to water and then to steam; but none the less, it remains obvious that the world up to the present moment has had considerable causal orderliness. Now, is this something that calls for explanation?

In the mid twentieth century a widespread opinion was that explaining any one causal law, for instance that heated water changes to steam, could proceed only by appeal to some more basic causal law such as that faster-moving molecules find it easier to break free from one another. The very most basic laws could not possibly be explained, therefore. They would concern mere regularities: as a matter of brute fact, events of one kind would always (or very often) be succeeded by events of some other kind. Discussing the idea that various individuals can know hidden cards by "extra-sensory perception", A.J.Ayer (1970) writes that the only thing which would be remarkable here would be someone's being "consistently rather better at guessing cards than the ordinary run of people"; the fact of doing "better than chance" would prove "nothing at all". If everybody just did know all about playing cards without looking at them, then there would be no mystery in this.

Recently, many philosophers have found such an approach dissatisfying. It is usually ascribed to Hume (1739), yet Hume suggests that causation's patterns would have characterized various events which did not actually occur. As a matter of causal necessity, a window (for example) would have broken had a brick been thrown at it, or would have remained intact had a mere peanut been thrown. This is often thought obviously right, the problem then being how causal patterns could have a *necessity* which was not just a matter of what always in fact occurred.

Might physics and cosmology throw light on any such problem? Quantum theory suggests to many people that we should think in terms of propensities, tendencies, rather than of absolutely firm necessities (a brick might "quantum-tunnel" across a window without smashing it, but this would be exceedingly unlikely) and that the Big Bang grew from a "quantum foam" in which causation as ordinarily conceived could not have acted since there was no firm direction of time. But all this leaves the fundamental issue largely untouched. Why does our world ever obey anything worth the name of a physical law? Or, to express the point differently (Wigner 1960), why "the unreasonable effectiveness of mathematics in the natural sciences"? Why does our world have the kind of elegance which made Jeans (1930) talk of a mathematically minded creator? While no logically possible world could violate mathematical principles, it is easy enough to imagine worlds in which they had little application.

When authors present a divine person or divine creative principle as responsible for the world's existence, they sometimes view causal orderliness as a matter directly attributable to this person or principle (Swinburne 1968 and 1979; Leslie 1979). Whitehead proposed instead (1938) that all things in nature in some sense strive to achieve aims, even atomic particles enjoying some very low level of awareness -- a theme echoed by the physicist D.Bohm (Bohm and Hiley 1993, chapter 15).

Note that the alleged problem of why there are causal laws is rather different from the alleged problem of why anything ever moves or changes, which is what led Aristotle to propose a divine prime mover.

Design and Fine Tuning

Living organisms provide seemingly overwhelming evidence of divine design, their parts forming immensely complicated mechanisms which permit them to survive and to reproduce themselves. To say "That's how they just happen to be" would be silly, although Philo in Hume's *Dialogues*(1779), sometimes thought to speak for Hume himself, may at times be guilty of saying it. Had Darwin said it, then he would never have discovered his famous way of undermining the seemingly overwhelming evidence: his theory of evolution, that is to say. Darwin's theory is now known to be right, so supporters of design seek their evidence elsewhere. They point to how the world's laws combine to make Darwinian evolution possible (Henderson 1913 supplies an early example of this). Why, they ask, is there a friendly environment in which extremely complex living machinery could appear after long ages, through selective inheritance of more and more complicated genes?

They can here direct our attention not just to the general fact of causal orderliness as discussed above but also (Leslie 1989, chapter 3) to the fortunate effects of particular causal principles. Consider, for instance, the principles met with in quantum theory. As well as allowing apparently dissipated wave-energy to concentrate itself so that it can do useful work, quantum laws ensure that atoms come in standardized types, making the genetic code possible. Similar things can next be said of the laws of special relativity, and of various laws controlling elementary particles.

However, much more attention has been directed towards the apparent "fine tuning" of fundamental cosmic parameters: the strengths of physical forces, the masses of elementary particles, the expansion speed and degree of turbulence at early moments in the Big Bang, and so forth (Barrow and Tipler 1986; Davies 1982; Ellis 1993; Leslie 1989, chapter 2; Leslie ed. 1990; Polkinghorne 1986; Rolston 1987). For example, it appears that electromagnetism, gravity, and the two main forces which control the atomic nucleus, had all of them to have strengths which fell inside very narrow limits if there were to be any stars of the long-living, steadily burning sort: the sort which encourage life to evolve. Again, life's complex chemistry appears possible only thanks to very precise adjustment of the masses of the neutron, the proton and the electron.

For there to be life of any readily imaginable kind, anything up to several dozen factors can appear to have needed fine tuning. Because the number of factors to be listed seems so large, this supposed evidence of design can survive many doubts about what exactly should be on the list. Take the case of the early cosmic expansion speed. It is often held that cosmic inflation, a brief burst of tremendously rapid expansion occurring early in the Bang, resulted in a universe whose subsequent more leisurely expansion was in no need of tuning. Yes, the expansion speed after inflation had to fall inside very narrow limits for stars to be able to form but, it is often said, inflation more or less forced the speed to fall inside those limits. To this we might reply that inflation itself stood in need of very delicate tuning, yet we could instead simply drop the expansion speed from the list, pointing out that plenty of other items remained on it. [We could find the list impressive without claiming knowledge of all logically possible universes, most of them presumably with properties very distant from those of our universe, and of what proportion of these possible universes were life-permitting. Imagine that a bullet hits a fly surrounded by a large empty

area. The bullet's trajectory needed fine tuning to achieve this result, which can help to show that a marksman was at work. It can help to show it regardless of whether distant areas are all of them so covered with flies that any bullet striking them would hit one. The crucial point is that *the local area* contained just the one fly.]

It is sometimes held that we could avoid belief in fine tuning by believing instead in various exotic life-forms (Feinberg and Shapiro 1980). Rather than being based on chemistry (which means, in effect, on electromagnetism), intelligent organisms might be based on the strong nuclear force so that they could inhabit neutron stars. Alternatively, they might be plasma beings inside the sun, or complex patterns in frozen hydrogen, or intricately organised interstellar gas clouds. None of these intelligent life-forms would dream of arguing that chemistry, something possible only through fine tuning, was necessary to intelligent life. Yet people willing to believe in such strange life-forms could still say that much tuning was required for there to be neutron stars, suns, planets covered with frozen hydrogen or interstellar clouds. It is often reasoned (see Rozental 1988 in particular) that a universe taken at random from among the apparent physical possibilities would almost certainly lack such objects. It would be likely either to collapse in a Big Crunch after a very brief, intensely hot career, or else to expand so fast that any matter which it contained soon became too rarefied to form clouds, let alone stars and planets. It could well consist almost entirely of light rays or black holes.

Various other doubts about fine tuning and the need to explain it are fairly easily dismissed. For instance, it seems wrong to reason (i) that no possible evidence of design could have any force *because we can see only the one universe*, and therefore cannot know whether its patterns are at all extraordinary, or (ii) that all possible patterns *would be equally probable*, just like all possible hands of cards, or (iii) that *probabilities depend on repetitions being possible* whereas the universe is unrepeatable: a universe can occur only once. Such reasoning delivers the strange conclusion that not even the words "God designed all this", written on every rabbit, tree and snowflake, could be in special need of explanation. It forgets such facts as that a hand of cards which includes four queens, four kings and four aces can, thanks to the possibility of cheating, be considerably more probable than many others. And the claim "that a universe can occur only once" itself runs into trouble: see the next section, "Multiple Universes".

Again, it would surely be wrong to protest that fine tuning needs no explanation "since if the universe hadn't been tuned in appropriate ways, then there'd not have been anybody to consider the affair". What would you think of the man who, untouched by all the bullets of a fifty-marksman firing squad, failed to suspect that the marksmen had wanted to miss him, commenting instead "that he'd otherwise not be alive to discuss anything"?

A divine designer's influence might be limited to creating a universe with life-permitting laws and fine-tuned force strengths, particle masses, etcetera. Some (e.g., Ward 1996b) argue, however, that God could be expected to influence the course taken by Darwinian evolution, ensuring that various crucial events occurred in favourable ways. [Assuming that quantum physics makes the reign of natural law into something only probabilistic, not deterministic, then there is actually some difficulty in deciding whether God, by ensuring that such and such an event occurred in the most favourable of various ways which quantum physics allowed, would be "intervening miraculously".] Also, it is sometimes thought that God

created a universe in which the evolution of intelligent, truly conscious minds, and the workings of those minds during free decision-making, are at least in part inexplicable by physical laws (Swinburne 1986).

Multiple Universes

If by "universe" you mean Absolutely Everything, then there must be just a single universe. However, people often picture the cosmos as containing numerous huge domains, very varied in their characters and largely or entirely isolated from one another. Now, "universes" is what they typically call them nowadays. Understood in this way, universes can be used to explain any observed fine tuning without introducing a divine designer. While most universes could well be hostile to intelligent life, observers would clearly have to find themselves in the life-permitting ones.

Numerous universe-generating mechanisms have been proposed (Atkins 1992; Barrow and Tipler 1986; Barrow 1988; Halliwell 1992; Leslie 1989; Leslie ed. 1990; Linde 1990; Rees 1997; Rozental 1988; Smolin 1997). Universes could be successive cycles of an oscillating cosmos (Big Bang, Big Crunch, Big Bang, etcetera). They could be huge areas of a gigantic, perhaps infinite cosmos. They could be the "worlds" of Many-Worlds Quantum Theory, which says that reality continually branches, every alternative allowed by quantum laws occurring in some branch or other. They could be quantum fluctuations in a pre-existing space or in a space-time foam. Or they might "quantum-tunnel from nothing" (if that makes sense), or bud off from other universes, or form bubbles in which expansion speeds had slowed inside a cosmos which was perpetually inflating. They could even be born in the depths of black holes, then expanding into spaces of their own without disturbing their parent universes.

All this could help an opponent of divine design only if the universes differed widely so that sooner or later, somewhere, one or several of them might be expected to be fine tuned in life-permitting ways. Difference-generating mechanisms are easily invented, however. An early suggestion was that an oscillating cosmos would "forget" its properties in the quantum-fuzzy depths of its Big Crunches. Among many later suggestions, perhaps the most plausible is that tiny domains form in the cosmos like ice crystals on a pond, each domain then being enormously enlarged (to "universe size") by cosmic inflation so that living beings deep inside it cannot see the other domains. Wide differences between the domains can readily be attributed to *scalar fields*. Having no directionality such as makes a magnetic field obvious to a compass needle, scalar fields are hard to detect, yet it is now standardly considered that such fields tore apart the initially unified forces of nature (electromagnetism and the nuclear forces, for instance) and gave them their various strengths, also causing various types of particle to become massive to differing degrees. Appearing early in the Big Bang, the scalar fields could have differed randomly from place to place because different field intensities were more or less equal in their potential energies (which are what physical systems try to minimize, like balls rolling down into valleys).

Belief in multiple domains, alias universes, and in the likelihood that they differ widely, is nowadays extremely common among cosmologists. It is considered quaint to assume that all of reality must be like the region visible to human telescopes. This would have pleased Hume's Philo, who cautioned us against any such assumption (Hume 1779). A reality consisting of infinitely many, very varied universes may

actually be thought simpler than the alternatives. Why, after all, should a universe-generating mechanism operate only a limited number of times? And if it operated again and again, why should it produce identical results on each occasion?

This does not mean that belief in divine design must be abandoned. While the manner in which our universe appears "fine tuned for permitting life to evolve" could encourage a story about many widely differing universes, it could equally well support belief in a designer. The fact remains, though, that the designer does not supply the sole plausible explanation for any fine tuning. This is largely because universes, like ice crystals, could differ widely while remaining identical in the fundamental laws they obeyed.

The Anthropic Principle

In the early 1970s, Brandon Carter stated what he called "the anthropic principle": that what we can expect to observe "must be restricted by the conditions necessary for our presence as observers" (Leslie ed. 1990). Carter's word "anthropic" was intended as applying to *intelligent beings in general*. The "weak" version of his principle covered the spatiotemporal districts in which observers found themselves, while its "strong" version covered their universes, but the distinction between spatiotemporal districts and universes, and hence between the weak principle and the strong, *could not always be made firmly*: one writer's "universe" could sometimes be another's "gigantic district". Moreover, the necessity involved was never -- not even in the case of the "strong anthropic principle" -- a matter of saying that some factor, for instance God, had made our universe *utterly fated* to be intelligent-life-permitting, let alone intelligent-life-*containing*. However, all these points have often been misunderstood and, at least when it comes to stating what words mean, errors regularly repeated can cease to be errors. Has Carter therefore lost all right to determine what "anthropic principle" and "strong anthropic principle" really mean? No, he has not, for his suggestion that observership's prerequisites *might set up observational selection effects* is of such importance. Remember, it could throw light on any observed fine tuning without introducing God. Everything is thrust into confusion when people say that belief in God "is supported by the anthropic principle", meaning simply that they believe in fine tuning and think God can explain it. As enunciated by Carter, the anthropic principle does not so much as mention fine tuning.

Being aware of possible "anthropic" observational selection effects can encourage one set of expectations, and belief in God another set. If suspecting that Carter's anthropic principle has practical importance, you will be readier to believe (i) that there exist multiple universes and (ii) that their characteristics have been settled randomly, some mechanism such as cosmic inflation ensuring that all was settled in the same fashion throughout the region visible to our telescopes. True, the believer in God can accept these things too, yet he or she may feel far less pressure to accept them. Even if there existed only a single universe, God could have fine tuned it in ways that encouraged intelligent life to evolve.

A possible argument for preferring the God hypothesis runs as follows. A physical force strength or elementary particle mass can often seem to have required tuning to such and such a numerical value, plus or minus very little, *for several different reasons*. Random variations from universe to universe might

explain why it took any particular value somewhere or other, yet how could they account for the fact that one and the same value satisfied many different requirements? Why is such consistency possible? Why does electromagnetism, for example, not need to have one strength to allow atoms to be stable, and another strength for stars to burn at a life-encouraging rate, and yet another to permit carbon (quite probably crucial to life) to be produced plentifully? Here a religiously minded physicist could think in terms of many possible fundamental theories, God selecting a theory which permitted life's requirements to be fulfilled without contradictions.

God

It is sometimes protested that God cannot adequately explain the existence and orderliness of the cosmos, for the following reason: that God's own existence, and the orderliness which would have to characterize his mind before he could bring order to anything else, would in turn need explanation. How might theists reply?

It might seem that an infinitely knowledgeable divine mind would be infinitely harder to explain than any finite cosmos or than one which, while infinite in both time and space, was still limited in, for example, the number of its dimensions -- whereas the divine mind would know every possible universe, including those with a million billion dimensions. Again, such a mind might be thought to go infinitely far beyond any evidence we could collect. [If you saw a pound of butter rising on a balance pan, would you conclude that it was being outweighed by an infinitely heavy weight?] It can be replied, however, that an all-knowing mind *would be in a way extremely simple*, as can be seen by how a single word -- "everything" -- can describe what it knows; and such an all-knowing mind, it could next be said, might well be expected to create a complex cosmos for the sake of all the living beings in it. But while the combination of the cosmos and a divine creator might be considered simple for reasons such as these, there remains the difficulty that a complete and utter blank could well be thought simpler still. Note that the "ontological argument" which tries to prove God's existence from his mere notion is generally dismissed today. There would seem to be no contradiction in the idea that a perfect being *was a logical possibility only*, not an actual existent.

On the other hand, logical possibilities can be *real* without being *actual existents*, and once this is appreciated their reality can be seen to be guaranteed. If God or anything else is a logical possibility, then that is an unconditional fact. It is eternally the case, non-fictitious, genuine, real, that this or that is indeed a logical possibility. [How odd it would be to fancy that thinkers, for instance, could become *really logically possible* only after they had come into existence and developed logics! Before thinkers evolved, the sun which helped them to evolve was logically possible, surely. It was not like a round square, and nor were the thinkers.] Furthermore, some logical possibilities are such that their failure to be actualized -- their absence from the realm of actually existing things -- can be thought needed, ethically required, in an eternal and unconditional way. Take the case of a logically possible world consisting solely of people in torment. To declare that the actual existence of such a world would be evil is the same as calling its non-existence needed or ethically required, and it could seem utterly wrong to add "just so long as there exists somebody who is contemplating the affair, somebody with a moral duty to prevent the existence of such a

world". Likewise, to say that a world full of interest and happiness would be a good thing is to say that the existence of such a world is ethically required, and would (presumably) be so regardless of whether anyone ever contemplated that fact. Might we point to these matters when trying to account for the existence of God or of the cosmos?

Certainly, the concept of an ethical requirement is distinct from that of a requirement which is fulfilled; yet cannot a flower be red, despite how the concept of redness differs from that of being a flower? Flowers are "the right sort of reality" for being red. They are "in the right ball park". The idea of a red flower is not conceptually confused. And rather similarly, it can be argued, a requirement for the existence of something, for instance a divine mind, might be the right sort of reality to carry responsibility for this something's actual existence, *even if it were an ethical requirement*. There is no conceptual confusion here. So long as it was recognized that no logical necessity was involved, it could actually be suspected that some ethical requirement (or consistent set of requirements) carried such responsibility *necessarily*. Compare, perhaps, the necessity that red as we experience it (say, in an after-image produced by a bright light) is nearer to purple than to blue. This can be argued to be an absolute necessity, without being a logical necessity. Again, it can be argued that various states of mind are necessarily in themselves worth having, without this being logically demonstrable.

An ethical requirement is, at any rate, what Ewing (1973, chapter 7) proposes as the ground of a divine person's reality. As a matter of necessity -- necessity which is absolute despite not being provable by logicians -- the unconditionally real ethical need for a divine mind to exist is adequate, Ewing suggests, to ensure its eternal existence. And a very similar theme is central to the long neoplatonic tradition in theology. This treats "God" as the name not of any mind, but of the supposed fact that the world owes its existence to its ethical requiredness (Leslie 1979, 1989 chapter 8; Mackie 1982, chapter 13; Levine ed. 1997; Tillich 1953-63).

Ewing's picture may at times be hard to separate from that of the neoplatonists. For suppose we joined the pantheist Spinoza in thinking (to take an interpretation of his writings which can seem to make sense of them) that all the complexities of the cosmos are simply the complex thoughts of a divine mind, so that your consciousness and mine, or the consciousness of a bird or of a bat, is just the divine knowledge of what it is like -- exactly what it feels like -- to be particular living beings with strictly limited power and knowledge. Suppose we also adopted the belief (which can again be the suggested by Spinoza's writings) that the divine mind exists *because this is ethically required*, rather than through any logical necessity which has nothing to do with good or bad. There might then be no real difference, so far as concerned the situation in which we believed, between our declaring (a) that God was a divine mind, as Ewing thought, or (b) that God was the cosmos, as Spinoza thought, or (c) that, as neoplatonists think, God is a creative force or principle: the principle that a supreme ethical requirement (or consistent set of requirements) is responsible for the existence of the cosmos.

Sure enough, this disregards distinctions which have appeared important to many people. For many variants on pantheism and on neoplatonism, consult Forrest (1996), Laird (1940), Levine (1994) and Whitehead (1938). Sometimes Spinoza's eternal and all-knowing divine mind is replaced by one which constantly improves its power and its knowledge. Sometimes God is thought to some degree separate

from the cosmos, instead of just being the cosmos or the creative ethical requiredness of the cosmos. Sometimes the notion that the natural world is alive, and that it strives after value, plays a greater role than the idea that value is actually achieved. Sometimes identification of the cosmos with God is oddly taken to imply the illusoriness of most of the things we think we see.

Time and the Human Mind

Believing (as Spinoza appears to) that we are all parts of a divine mind, we might think we could answer the theological problem of evil: the problem of why the cosmos contains so many items which can seem so very unsatisfactory. Knowing everything, or (if this is different) everything in the least worth knowing, a divine mind could know many things which might be very little worth knowing if they were taken in isolation. It might know, for example, not only all the detailed structure of innumerable universes, but also exactly how it would feel to be each of the intelligent living beings in those universes. Knowing this eternally, it could none the less know what it felt like to be engaged in actual struggles, in constant ignorance of what the next moment would bring: see Williams (1951) to gain further insight into the theory about time's flow which would be involved here, a theory often adopted because it appears to reflect Einstein's theory of relativity. While such items of knowledge might be nowhere near the best that it possessed, the divine consciousness could still be better for not being ignorant of them.

A competing approach to the problem of evil is often preferred, though. Instead of viewing themselves as elements of a divine mind, many religious people think they exist separately from that mind and are given absolutely free choice of whether to join it in a heavenly hereafter.

Absolutely free choice, as they conceive it, depends on time's flowing in a way which Einstein rejected when he wrote of the world as having "a four-dimensional existence". [Suppose that you are about to choose "with absolute freedom" whether to give up smoking. It cannot already be true, they say, that "at points a little further along the fourth dimension" you are lighting a cigarette.] It probably also demands a fairly strong division between the operations of human minds and those of material objects.

Extraterrestrials

Belief in God need not involve believing that our universe is crammed with intelligent life from side to side and from start to finish, or that God will save humans from driving themselves to extinction through polluting their planet or by germ warfare, or perhaps (Rees 1997, chapter 12) by experiments at extremely high energies. The fraction of our universe which we can see contains many hundred million trillion sun-like stars. Even if only a small proportion of these had hospitable planets, intelligent beings could well exist in tremendously many places. What is more, the universe as a whole might be very much larger, perhaps infinitely larger, and there may be up to infinitely many other universes. Wishing for intelligent beings to exist in large numbers, a divine person could have them without ensuring that humans survived long enough to colonize their entire galaxy.

We have failed to detect extraterrestrials, although calculations suggest that an intelligent species could spread across its galaxy in a few million years. This, together with our observed position in the midst of a population explosion, might reinforce whatever other grounds we had for thinking that rapid extinction, not galactic colonization, was the likely fate of an intelligent species. Suppose human extinction occurred during the next century. Roughly ten per cent of all humans who had ever been born would be alive when it occurred. On the other hand, if humans spread right across their galaxy then perhaps well under a thousandth of one per cent would have lived during that period. This may be found disturbing. [The point is that one ought to hesitate before adopting theories whose truth would have made one's own observations highly unlikely, when other theories would have made them fairly likely. It is a point first noted by Brandon Carter; for a discussion drawing very pessimistic conclusions from it, see Gott (1993). Various reasons in favour of guarded optimism are given by Leslie (1996), reasons centred on the fact that our universe is probably indeterministic, so that the number of humans who will ever have lived is something which has not yet been fixed.]

For religious people asking whether humans will soon be extinct, here is a point to bear in mind. If you hope to solve the theological problem of evil, then you have to assume that there are strong reasons *against* divine intervention to prevent calamities.

Immutability

The doctrine of divine immutability (DDI) asserts that God cannot undergo real or intrinsic change in any respect. To understand the doctrine, then, we must first understand these kinds of change. Both "intrinsic" and "real" (in the relevant sense) are hard notions to elucidate. I cannot here attempt anything like a full account of them. I instead provide very rough characterizations, which would be acceptable on a wide variety of competing accounts of these notions.

1. Kinds of Change

A change is real if and only if it makes on its own a real difference to the world. Real change is (roughly) change involved in causing something, change an item is caused to undergo or change not "logically parasitic" on change in other things. (These "or"s are inclusive, not exclusive -- one change can satisfy more than one clause of this account.) Smith's kicking me involves changes in Smith. Kicking me makes on its own a real difference in Smith. When Smith kicks me, I undergo various changes which count as real, intuitively -- being kicked makes many real differences in me. On the other hand, when I become shorter than Smith because Smith grows, Smith changes really but I do not. Gaining height makes a real difference in Smith, but Smith's gaining height doesn't make a real difference in me. Rather, my becoming shorter than Smith in this way is logically parasitic on Smith's growing. It is simply a logical consequence of a real change in something else, not a real change itself.

Coming at the notion another way, a change is real if and only if it is an event which logically could be either the only event that occurs in an entire universe or else the sum of all events in a universe, while a change is a "logical parasite" if and only if this is not true of it. Consider Smith's kicking me. This looks like it could be the only occurrence in a universe. It is logically possible that the universe simply sits there wholly static, then Smith kicks me, then the universe winks out of existence before anything else happens. But actually, when we look more carefully, we see that in this case, the kick is not the only

change. For it has parts which are shorter or spatially smaller changes. In the kick, for instance, Smith's leg first moves an inch, then another inch, etc., and each movement consists spatially of discrete movements by various muscles. The kick is not the only change, but in the odd universe I described, it is the sum of all changes in a universe. No change with parts can be the only change in a universe, strictly speaking. On the other hand, it is not logically possible that my becoming shorter than Smith in the way described occur alone or be a sum of all changes occurring in a universe. For it to occur, Smith's growth must also occur. And Smith's growth is not a part of it. So changes are real if and only if they are logically independent events in the world's history. If God cannot change really, then, nothing can so act on him as to change him, his actions do not change him, and no change in God could be the only event in a universe. If God cannot change really, then if had there been nothing other than God, there would have been no change at all, of any sort.

Intrinsic changes are changes like learning or expanding, which (roughly) occur entirely within the changing item -- which could occur if the universe ended at the item's "skin." Putting this more carefully, a change is intrinsic to the changing thing if and only if its occurring does not imply the existence of anything "outside" the boundaries of the changing thing. Changes which are not intrinsic are extrinsic. All changes in relations to other things are extrinsic. For instance, if a dog moves to my left, I become a man with a dog on his left. This does not take place wholly within me. It also involves the dog, who exists outside me; it implies the existence of the dog.

Changes can be intrinsic or extrinsic in spatial or temporal terms. The dog's coming to be on my left is a spatially extrinsic change in me. If Smith's guardian angel gets angry at Smith's kicking me an hour earlier, this change has no spatial aspect -- angels have no spatial location or boundaries. But it is a temporally extrinsic change in the angel, for it implies the occurrence of an event, the kicking, which occurred outside the temporal boundaries of the becoming-angry. Extrinsic changes aren't "real" in the sense above. I change extrinsically when a dog comes to be on my left. The dog does not so act on me at to make me have it on my left: the dog does nothing to me at all. And my becoming a man with a dog on his left could not be the only event in a universe. For it to happen, a dog must also move. But to say that extrinsic changes aren't "real" in the above sense is not to say that they don't occur. It is merely to classify them.

DDI lets God change extrinsically. On DDI, God can, e.g., come to have new relational properties involving other things which are not due to those things' acting on him. Suppose that at *t*, Quine worships God. Then at *t*, God comes to have a new relational property, being-worshipped-by-Quine. This is clearly an extrinsic change, since its occurring in God implies the existence of someone "outside" God, namely Quine. God does not (let's say) do anything to cause this. It's a matter of Quine's free will. Quine doesn't do anything to God by worshipping him. And this change in God is a logical parasite of the real changes in Quine which constitute his worshipping God. It's not possible that becoming worshipped by Quine be the only change in a universe. Quine's worshipping must occur too if this one does. DDI thus lets God become Quine-worshipped. It rules out only real and intrinsic changes.

All of this raises a question: why do only real, intrinsic changes matter? It would be silly to ascribe to friends of DDI some sort of pre-given general antipathy against real, intrinsic change. Disliking change

makes as little sense as disliking qualities or relations. DDI's friends simply followed various specific arguments, discussed below, where they seemed to lead. And they seemed to lead to a denial that God can change really and intrinsically, but not to a denial of all divine change *tout court*. The arguments which led philosophers to exempt God from real, intrinsic change all had to do with ways involvement in change might (they thought) make God less perfect. It isn't plausible that merely extrinsic change could make something more or less perfect. I am exactly as impressive a man with a dog on my left as I am without a dog on my left.

2. Immutability vs. Impassibility

DDI is sometimes conflated with the doctrine of divine *impassibility*, which asserts that nothing external can affect God -- that nothing external can cause God to be in any state, and in particular can cause him to feel negative emotions like grief. Actually, DDI neither implies nor is implied by divine impassibility. Something could be impassible but mutable if it could change itself, but nothing else could change or affect it. God could be immutable but passible. For he could be changelessly aware of events outside himself -- perhaps even caused to be aware of them by the events themselves -- and due to them changelessly feel such responsive emotions as grief. But he would feel them without change, and so always feel them. If temporal, such a God would grieve for us before, while and after we suffer what he grieves for. There is nothing counter-intuitive in this. It's standard theism to hold that God has full foreknowledge of what is to befall us: he sees our pain before we feel it, not just while we feel it, and so grieves it beforehand if He ever grieves it at all. There would be no difference in the quality of God's grief before and while the pain occurs. For were there anything about it He did not know beforehand, the foreknowledge would not be full, and full knowledge beforehand should elicit the same reaction as full knowledge during. Likewise, it's standard theism to hold that God is cognitively perfect. If he is so and exists in time, He has a past to recall and so has perfect memory. If God perfectly remembers your pain, it is as fresh for him years later as it was while it occurred, and if he perfectly loves you, perhaps he never gets over it. So we can make sense of unchanging grief; if God does grieve, we might well expect it from a God with full foreknowledge, cognitive perfection and a perfect affective nature. If He is timeless, an immutable but passible God would just timelessly suffer for us -- responsively, i.e., because of our pain. The case would be just as if God were temporal, save that His knowledge would not be temporally located and so would not literally involve either foreknowledge or memory. So whether God is temporal or timeless, DDI implies nothing odd here. And it need not "depersonalize" God as some feel impassibility would.

Still, it is surprising that Western theists have held DDI. For Western Scriptures seem to conflict with the full DDI. Some Scriptural texts depict human sin as making God sadder than he was (e.g., Gen. 6:6), then bringing God to new decisions, e.g., to flood the world. According to *John*, "the Word became flesh" (1:14), i.e., God took on a human nature he did not always have. So Western theism's Scriptural roots seem to deny DDI. Yet by the first century A.D., DDI was central to the main theory of God's nature, "classical theism." In such "classical theist" writers as Augustine and Aquinas, being immutable makes God eternal, and eternality is God's distinctive mode of being. So DDI is at the roots of such writers' understandings of God's nature. And "classical theism" ruled the theological roost till the 19th century. So

one wonders: what made DDI so attractive for so long?

3. The Case for Immutability

For one thing, the Scriptural witness is not really so thoroughly on the side of divine real intrinsic change. Much that Scripture says of God is clearly metaphor. And it is not hard to show that Old Testament texts which ascribe change to God could be speaking metaphorically. As I note later, one can parse even the Incarnation in ways which avoid divine real or intrinsic change. Standard Western theism clearly excludes many sorts of change in God. Western theists deny that God can begin or cease to be. If God cannot, He is immutable with respect to existence. Nothing can change its essential nature: a thing's essence is by definition a property (or set of them) it cannot fail to have. For Western theists, God is by nature a spirit, without body. If he is, God cannot change physically -- he is physically immutable. So it is not clear that the Western God could undergo other than mental changes -- changes in knowledge, will, or affect. Further, Scripture amply supports the claim that God is in all respects perfect. In conjunction with certain other Scriptural claims, God's perfection seems to rule out many sorts of mental change.

This is a broader topic than can be tackled here; instead, a few examples involving God's knowledge will be examined. If perfect, God is all-knowing. If God learns something new, then before that he was not all-knowing, unless the new item could not have been foreknown. Only free beings' future actions and what depends on these are even *prima facie* beyond God's foreknowledge. But Scripture is full of claims that God foreknows our free actions. So if Scripture calls God's knowledge perfect and asserts that it includes foreknowledge, there is a sort of fact about which God is omniscient and his knowledge does not change. Suppose that today God knows that I will finish this article tomorrow and tomorrow God knows that I *am* finishing the article. There is a fact God knows both days, that on this particular day, referred to one day as "tomorrow" and another as "today," I finish the article. Such facts involve no real tense: they are ‘tenseless’ facts. If God has foreknowledge even of free creaturely actions, he always knows all tenseless facts. His knowledge of these does not change, and if He necessarily foreknows, then his knowledge of these is immutable. Our own knowledge of these constantly changes. I do not know till tomorrow that I tenselessly-finish the article tomorrow, for I do not know this until I know that I *am* finishing it, a truth which is present-tensed rather than tenseless. Similarly, if God always knows all truths of mathematics and logic, his knowledge of these never changes, and here too it is plausible to suppose that His knowledge of these cannot change. For these truths are necessary. Truths of mathematics and logic cannot be or become false. So God could change with respect to his belief in these only if he could at some time hold a false belief. If God is necessarily omniscient, he cannot.

Unlike us, then, God has a constant, unchangeable store of tenseless knowledge about all of history, mathematical knowledge, logical knowledge and indeed knowledge of any other sort of necessary truth -- and this on Scriptural grounds. It is a small step indeed from divine perfection to necessary divine perfection. For it is surely more perfect to be unable not to be perfect than to be perfect but able not to be. Again, it is a small step from foreknowledge to necessary foreknowledge: wouldn't the latter be more perfect? So God's necessary and tenseless historical knowledge -- tenseless knowledge of contingent truths -- looks to be unchangeable, given only a small step beyond Scripture. We can take this a step

further. The only sort of knowledge we've left out so far is knowledge of tensed contingent truths -- such truths as that tomorrow I *will* finish the article or yesterday I *did* finish the article. If God always knows the tenseless correlates of these truths -- e.g., that on March 27, 2002, it is the case that I tenselessly-finish the article on March 28, 2002 -- then his contingent knowledge changes only in ways for which the passage of time accounts. For which tensed truth God knows -- that I will finish, am finishing or did finish -- depends simply on what time it is. So to speak, he never has to learn about whether I finish on March 28; he merely has to learn where in time he is in relation to March 28, and this tells him what tensed propositions are true about my finishing. Thus one can make a case on what are basically Scriptural grounds that God's knowledge changes at most due to the bare passage of time.

So Scriptural considerations suggest a God at least much less changeable than we in some respects. But the roots of the full DDI are also philosophical. In thinking out their views of God's nature, Western philosophers have largely filled out the concept of God by ascribing to him the properties they thought he must have to count as absolutely perfect. God's perfection seems to rule out many sorts of change, as we've just seen. More general arguments from perfection convinced classical theists that God cannot change in any way.

Plato argued for the full DDI. He asserted that a god is "the… best possible" in virtue and beauty. Virtue is a perfection of mind. Beauty is a non-mental perfection. So Plato's examples are probably meant to do duty for all mental and non-mental perfections, i.e. all perfections *simpliciter*. If a god is already the best possible in these respects, Plato reasoned, a god cannot change for the better. But being perfect includes being immune to change for the worse -- too powerful to have it imposed without permission and too good to permit it. Thus a god cannot improve or deteriorate. Plato's argument had great historical influence. But it overlooked the possibility of changes which neither better nor worsen. If one first knows that it is 11:59:59 and then knows that it is midnight, is one the better or the worse for it? If the best possible state of mind includes omniscience, then perhaps it includes constant change in respects which neither better nor worsen God, e.g., in what precise time God knows it is. Perhaps changes to 'keep up with' time are required by a constant perfection, his omniscience. At 11:59:59 it is surely better to know that it is now 11:59:59, and then at midnight it is better to know that it is now midnight. Plato's argument does not rule out such changes.

Aristotle also contributed to acceptance of the full DDI. For many medieval theists accepted Aristotle's case for God's existence. Aristotle's *Physics* reasoned that if change occurs, it has a final source, an eternally unchanged changer. Aristotle's *De Caelo* added that something is eternally unchanged only if unchangeable. Later theists thought the role of first cause of change too lofty not to be God's. Writers who took Aristotle's argument or its descendants to prove God's existence found themselves committed to DDI.

Boethius also played a role in DDI's popularity. He held that being in time involves, necessarily, at least two things which are defects. For being temporal, as Boethius saw it, entailed having past and future parts of one's life. Temporal beings no longer live the past parts of their lives. They do not yet live the future parts of their lives. Both things are defects, according to Boethius. So if God is free of all defects, Boethius reasoned, then God has no past or future. What has no past or future does not change. For what

changes goes from what it was to what it then was going to be, and so has a past and a future. Hence, to Boethius, perfection required changelessness. If it does, necessary perfection -- which is better than contingent perfection, and so by perfect-being reasoning is God's -- requires being immutable. Now Boethius' reasoning requires at least some cleaning up. For some things are temporal but have neither past nor future parts, e.g. instantaneous changes. And if one's past or future is a bad time, it is not obviously a bad thing not to be living them. But at least some current philosophers thing that Boethius' argument has a kernel of truth. For it would not be a perfection of an individual to have a life lasting only a single temporal instant. Surely longer would be better, at least if there was a good chance that the longer existence would be overall a good thing. And God's life, at least, cannot contain parts which it is overall bad to live if God truly is perfect.

Boethius actually followed his reasoning about divine perfection to the conclusion that God exists outside time by his very nature -- that God can't be temporal. For whatever has neither past nor future is not located in time. But change requires existence in time. Suppose that a turnip, aging, goes from fresh to spoiled. It also then goes from fresh to not-fresh. So first "the turnip is fresh" is true, then "it is not the case that the turnip is fresh" is true. The two cannot be true at once. So things change only if they exist at at least two distinct times. Hence, if God is necessarily atemporal -- via *necessary* divine perfection -- God is necessarily changeless, i.e. immutable.

Aquinas (like Augustine) derived DDI from the deeper classical-theist doctrine of divine simplicity. If God is simple, God has no parts of any sort. Now when the turnip aged, it became partly different -- its smell and texture altered. Were this not so, no change would have occurred. But if the turnip had changed in *every* respect, it would not have been a case of change either. For it would have changed with respect to such properties as *being a turnip* and *being identical with this turnip*. And if first we have something identical with this turnip and then we have something not identical with this turnip, the turnip has not changed, but disappeared and been replaced by something else. So whatever changes must stay partly the same (else there was not change in one selfsame surviving thing). So only things with parts can change. If so, a simple God cannot change. DDI's connection with divine simplicity and the classical theist theory of God's perfection which centers on divine simplicity is one of the deepest reasons for DDI's broad historical appeal; one cannot fully explain what moved thinkers to accept DDI without also treating the motivation for the doctrine of divine simplicity. That, however, is too large a topic to broach here.

DDI, then, has a variety of religious and philosophical roots.

4. Arguments Against Immutability

There are many arguments against DDI. One that some find particularly forceful begins from the fact that God is omniscient. If God is omniscient, they say, God knows what time it is now. What he knows, then, is constantly changing, since what time it is now is constantly changing. But knowledge of what time it is is intrinsic to God. And change with respect to something intrinsic is intrinsic change. So it seems that God cannot be intrinsically immutable.

One reply is that knowing the correct time is not an intrinsic state of God's. Intrinsic states are those settled entirely within one's own skin. But then unless *P* is a truth entirely about matters within one's own skin, knowing that *P* is not an intrinsic state. For that one knows that *P* rather than believes falsely that *P* only if *P* is true, and if *P* is not a truth entirely about matters within one's own skin, whether *P* is true is at least partly settled by matters outside one's own skin. But when it is now is not a matter settled within God's own skin. What time it is now is not a fact about God alone. It is a fact about time, which is not God, and also about the entire temporal universe. Further, it arguably is not the case even that what is within God's skin settles what time it is in the sense that were nothing else than God to exist, facts about God would suffice to determine what time it is. For this would be at best a contentious claim, as it implies that God would be in time if he existed alone, without a universe. Many would say that time is an aspect of the physical universe -- no universe, no time either. Moreover, even if God existed alone and were then in time, knowing what time it is would not be a *temporally* intrinsic matter. God knows that it is now *t* just at *t*. So knowing the correct time at *t* is temporally intrinsic only if it does not entail the existence or occurrence of anything that exists at other times. But for any time after the first instant (if there was one), knowing what time it is involves knowing the temporal distance between the present time and some other time: knowing that it is noon, April 16, 2002, implies knowing a relation between that time and date and the date traditionally assigned to the birth of Christ. Thus knowing what time it is entails knowing that there was some time other than the present -- a time outside the period in which God knows that it is now this time. Knowing what time it is at any time after the first instant thus is not a temporally intrinsic state. And if this is so, it is hard to see why even knowledge that it is time's first instant would be. Thus the objection has a false premise. If God's cognitive state with respect to what time it is changed, it would not follow from this that he is not *intrinsically* immutable. This result may seem a bit hard to swallow. One wants to know *how* a change in knowledge could fail to be an intrinsic change. One answer might appeal to externalist theories of mental content. On these, my knowledge that *P* is a complex consisting of my inner mental state plus certain items in the world. Perhaps God's knowledge that it is now *t* is something like a complex consisting of God's inner cognitive state and an external component, *t*. If it is, perhaps the only change involved when God first knows that it is now *t* and then knows that it is now t^* ($> t$) is the change from *t* to t^*.
